What works best in an 8877 does not work at all with a 3CX1200A7. The
design is dependent on the self-neutralizing frequency of the tube and the
layout.

>If an 8877's VHF parasitic oscillation suppressor resistor is 50 ohms
and
>the (paralleled) suppressor inductor is 30 ohms, the lion's share of the
>VHF current would seemingly pass through the 30 ohm inductor and the
>lesser, remainder of the total current would seem to pass through the
>resistor. However, perhaps I am in error.

Actually, if the grid is properly grounded and the anode leads are short,
the 8877 requires no suppression at all in many cases. When it does
require suppression, it is generally at UHF. So that would be a poor case
study of VHF suppression.

> Tom: Are you suggesting that the primary path of VHF current is through
>the paralleled 50 ohm resistor? If you maintain that most of the VHF
>current passes through the 50 ohm resistor, Tom, please show us the
>mathematical solution that led you to your conclusion.

Let's look at a typical suppressor such as the SB-220, AL-80, or SB-1000
suppressor, since a 3-500Z almost always needs a suppressor in the 100-
130 MHz area. Will that be ok?

3026. Is it possible to modify VCR "Rabbits" for ATV use?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-18 00:00:00 UTC
From: "Jon Arndt (N0SGM)" <holmes@concentric.net>
Message-ID: <01bbd4fe$ad9c3d60$bd72adce@default>
Source record: 100612

1. Is it possible to modify an ordinary "Rabbit" for ATV use?
2. Can the receiver module be modified to tune across the entire 902 Mhz band?
3. Can the transmit module be modified to xmit in the 1200Mhz band by multiplying the IF differently?
4. If the above is possible can the receive module be modified to tune the 1200 Mhz band?

Any suggestions would be appreciated.

Jon Arndt (N0SGM)

Many times :-)
Try using two micro switches back to back and mounted on a very small
board complete with strap and some 'Velcro', remember seeing it in a
recent QST.

Good news.
Fellow surfers, you could order real cool T-shirts or/caps with
a fantastic embroidery on: the graphic is a surfer surfing on www,
embroidered like waves on the sea in the virtual world, the word
cyber-surfer is lively located on the corner of the design. The whole
embroidery creation is just a piece
of art that reflects your spirit and your feeling.(Three colors of the
design will change
according to the colour of your ordered garment.)
If you want to personalized the garments, please add one dollar to the
price and specify the fonts you like, we will embroider your name on.
If you do not care about our graphic but want a phrase to be embroidered
such as CYBER-PUNK, PUNK@WWW.NET, WILD NETTER, NET HACKER or whatever you
want, just write to us, we will make you excited.
Caps, white, black, blue, yellow, red, purple, green and
brown, with ajustable buckle one size fits all.
T-shirts, white, black, blue, yellow, red, ash and natural, with M, L,
XL & XXL.

Please give yourself a treat or give your loved one a personalized X-mas
gift!

Both the T-shirts and the caps only cost U.S. $7.5/ Cdn $9.5 including
postage (even international!)
Please order by mail with check or money order to Power Vision Embroidery
Co. The address is:
****
Power Vision Embroidery Co.
101-1600 Adelaide Street North
London Ontario N5X 3H6 Canada
****
Please write your return address as clear as possible for quick
delivery.
Thank you.

Hi, Monty.

I made a very tiny paddle for portable QRP work. I used some old switch
contacts from Turner CB-type desk microphones. Relay contacts snatched
from old open-frame relays could be used also.

Ian suggested using a spectrum analyser set to peak hold mode as a
means of getting an indication of what a signal does to its neighbors.

It's funny he should mention that. I did it just 2 weeks ago.
Unfortunately, I didn't take any quantitative measurements, I was
just playing around. I need to put the directional coupler in the
line soon and re-run the tests during a QSO looking out over 100 KHz.
I can then correlate the results to a 2 tone test.

I'll post the results when I have them.

I built one a while back, but I haven't used it much. One day I was in
the garage, and noticed the laminage on the edge of the workbench (an
old desk with fake formica top) was peeling off. I pulled it off and
tried to decide what to do with it, it seemed about the right
flexability for a key, so I picked up some microswitches out of the
junk box with both NO and NC contacts, I glued a piece of 3/8 or so
wood between the pieces of laminate, glued that to a piece of PC board
perfboard, and mounted the two microswitches so the laminate held them
open, and connected the wires to the NC contacts. I put a piece of
velcro on the bottom, and stuck it to the console. It seemed OK, but
I'm not spoiled by something like the brass racer, I have a Scotkey
which is interesting, but not that good of a key. I don't know the
life of the microswitches either.

Good luck, if you come up with a design you might post it. One group
built a straight key out of hacksaw blades, and published it in QST a
few years ago.

[snip explanation pre-/de-emphasis used to increase signal/noise ratio]
>Similar schemes are used in tape decks, and on vinyl records (RIAA
>equalization, also called 75us equalization).

For vinyl, the maximum undistorted recording level depends on frequency,
so the RIAA equalization is tailored to reflect that, rather than simply
matching the signal and noise spectra. I thought it was more complex
than the simple 75 (or 50? depending which ITU region you're in) microsecond
curve generally used for FM?

>Dolby is a similar scheme.

Not really, except that its effect is to increase the S/N ratio -
unlike passive filtering, it works by active compression/expansion of
the signal (either just the high frequencies, or in several bands, depending
on which kind of Dolby you use.)

....snip...
>
> The Chinese tubes have poor fitting components (like anode connectors),
> gas troubles, and weak envelopes....snip......

The weak envelope problem in Chinese 3-500Zs was reported to QST staffer Rus Healy, NJ2L, by Vectonics, a Canadian Manufacturer of HF amplifiers. Rus told me that the glass would mysteriously melt in certain areas for no apparent reason. Naturally, the molten glass is forced towards the vacuum by the atmospheric pressure, until the resultant glass bubble pops. This problem appears to have been caused by an intermittent oscillation condition somewhere around 150Mhz. The cure was to improve the dampening ability of the VHF parasitic suppressor by lowering its VHF-Q.
Since Eimac 3-500Zs have not, to my knowledge, ever had such a problem during intermittent VHF oscillations, chances are that Eimac uses a glass recipe which provides a minimal dissipation-factor (D-factor) at VHF.

The Chinese amplifier-tube manufacturers are not exactly 'pretenders', Duncan. A tube dealer told me that Eimac engineers went to China--at the request of the U.S. Government--and showed the Chinese how to manufacture 3-500Zs, et cetera. I have a friend who services commercial FM broadcast transmitters that use 8877s. He tells me that the currently-made Chinese 8877s last as long as the Eimac 8877s. This was not the case in the beginning.

An approuch I saw a long time ago in QST which I tried and liked was
to bolt two regular practice straight keys (J-38's were $1.25 apiece then,
but any practice key would do.) back to back on a piece of 3" aluminium
Tee bar which is then strapped to the transmission hump of the car or
ballasted with a railroad sleeper plate and sat on the seat. The two
sides of the key are independently adjustable for spacing and tension and
even cheapie keys will hold up for a long time once you get the
adjustments right. KA1UL

How about two microswitches back to back with a piece
of (whatever) in between. Or you could mount the micro-
switches on a T with the handle sticking out. Just
make sure you can operate safely while driving.

I'd certainly like to hear an detailed explaination of how parasitics cause glass to fail, that might be as interesting as the photon tale.

BTW, all the Chinese 8877's I saw were relabeled Eimac tubes, some with manufacturing dates (in the serial numbers) as much as 8 years old. It doesn't surprise me life improved after they went through the old tubes and got into newer batches, since the early ones were from batches manufactured when Eimac had G-K shorts from heat dam and material troubles.

Many articles using air-wound coils direct one to short unused turns,
and you do too. I see how the voltage would be high at the end, like a
Tesla coil, but it seems like it would also lower the Q, possibly a lot.
Shorting unused turns on an inductor-with-a-core amounts to having a
transformer with a shorted secondary - which is no good! What
are the pros of shorting turns? (And how much does it lower Q?)

3045. Syncronous Noise Blanker Idea

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-18 00:00:00 UTC
From: frohro@wwc.edu
Message-ID: <frohro-1811961442450001@hrf.wwc.edu>
Source record: 100631

Hi,

The other day I had an idea. The idea was for a syncronous noise blanker. At home I am plagued by QRN coming from a substation about a mile north of my QTH. I've tried SEM's QRM Eliminator (which uses another antenna to pick up the nearby noise, adds it in with the signal from the main antenna, and amplitude and phase controls to sum the noise to zero), but it didn't solve my problem. I never could get another antenna to pick up the QRN from a mile away anywhere near as well as my four element quad.

So anyway, my idea is this: Assuming the noise is coming from arcing of a 60 Hz source, actually the same 60 Hz source I'm powering my radio on, and assuming it happens on peaks, then it will happen 120 times a second. Why not build a blanker that triggers on the 60 Hz line signal and that has an adjustable blanking interval time and adjustable delay from the trigger? Has anyone tried this? What kind of results were had?

Thanks!

>are the pros of shorting turns? (And how much does it lower Q?)
>
>Bruce

There is so much flux leakage in an air wound coil, Q reduction is not drastic. Especially since without shorting turns both series resonance and voltage breakdown problems get worse.

You may still have problems at the range above 15 MHz with unwanted series resonance, even with the unused turns shorted.

I will be off-net for two or three days.

BTW, Tom Brown keeps asking who my sources at Eimac were. I can not give that information out (as I have said) because they really don't want to be involved in this.
They did say they will consider making one more final statement as soon as they have time, if Mr. Measures agrees to accept their position as the final word on this subject.

Anyone doubting Eimac's position can investigate things on their own. I wouldn't wish the kind of technical nonsense being argued here on anyone.

My opinion is anyone believing fantasies about 25 watt grids handling 500 watts, VHF energy making tuning capacitors arc, VHF parasitics causing glass to melt, Photons making tubes on standby arc over, not understanding grid dissipation, and so on..... is far beyond any help I can offer.

This thread has outlived any usefulness.

3053. Re: Syncronous Noise Blanker Idea

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-19 00:00:00 UTC
From: commquart@aol.com
Message-ID: <19961119043400.XAA16888@ladder01.news.aol.com>
Source record: 100541

Interesting idea. Ideally, the blanking should
be applied well ahead of the IF filter stages,
preferably using a pin-diode attenuator right
at the RFA stage. You might consider using
multivibrator synced to the AC line, and having
some way to delay or advance the timing -- this
would allow you start the blanking at a precise
point on the AC crest just before the "breakdown"
that is causing the noise starts. Having a variable
blanking width might also be useful. Chances are once
the breakdown occurs, the arc will substain over a considerable
portion of the downside of the AC cycle due to the
conductive nature of the ionization of the air.
That may be the bugaboo -- the arc
duration may last for a considerable portion of the AC cycle.

Let us know how the project works!

BTW, Collins used a TRF receiver in the 40 mhz
range in their blanker design. Had the unit, but
never tried it.

Ralf,

I'm not sure what you mean exactly by semi rigid cable, if you want a very stiff Stainless Steel cable made of multiple wires, go to a marine shop specializing in Sail Boats, many of the cables are fairly rigid and all are Stainless Steel.

Hi guys (and girls)
I am looking for a winter project to keep me busy. I am looking for plans for a crystal control, tube transmitter (& PS) maybe 10 or 20 watts. I used to have old handbooks and such, but I can't find anything.

If you have a descent project please contact me by E-Mail and I will make arrangement to get them from you.

Thanks in advance.

> study of VHF suppression.

Who says that no suppression is needed for the 8877? The mysterious Mr. XXX? It is my opinion that this is porcine shampoo.
The gold-sputtered 8877 grid that is shown on page 16 of the Sept. 1990 issue of QST, was of a failed tube that was removed from a commercially-made 8877 HF amplifier that used a relatively high VHF Q parasitic suppressor. The failure occured during normal operation with normal drive. The failure did not occur during tuneup.
Tom: does the Alpha 77 8877 amplifier utilize a VHF parasitic oscillation suppressor?
Tom: does the Dentron DTR-2000 8877 amplifier utilize a VHF parasitic oscillation suppressor?
Tom: does Henry Radio utilize a VHF parasitic oscillation suppressor in their 8877 amplifiers?
Tom: does the Ameritron AL-1500 8877 amplifier utilize a VHF parasitic oscillation suppressor?

> > Tom: Are you suggesting that the primary path of VHF current is through
> >the paralleled 50 ohm resistor? If you maintain that most of the VHF
> >current passes through the 50 ohm resistor, Tom, please show us the
> >mathematical solution that led you to your conclusion.

Tom did not solve this problem. Apparently, Tom either 1. didn't have the time, or 2. he does not know how to solve this problem, or 3. he is fearful that the answer might jeopardize his title as one of the "amplifier experts". (See QST, Sept. 1994, page 71, col. 3)

The original problem:
==========
Tom has argued that virtually all of the vhf current passes through the suppressor resistor, and that virtually none of the vhf current passes through the suppressor inductor. Is this the case? In a typical 8877 vhf parasitic oscillation suppressor, the resistance is around 50 ohms and the inductance is roughly 45nH. A typical anode resonant frequency for an 8877 amplifier is about 100MHz. The reactance of a 45nH inductance at 100MHz is 30 ohms. If a 50 ohm resistance is connected in parallel with a 30 ohm inductance, which component will carry the most current, Tom?
==========
One solution: Apply 1VRMS to the parallel L-R circuit. The current through the R is 1V/50 ohms = 20mA. The current through the L is 1V/30 ohms = 33.33mA. The total current is 20 mA plus 33.33 mA = 53.33mA. Thus, 33.33/54.33 = 0.625, or 62.5%, of the total VHF current flows through the inductor, and 20/53.33 = 0.375, or 37.5% of the total VHF current flows though the resistor.

Tom stated:
> >>I've said repeatedly the primary path
> >> for VHF and UHF signals is through the resistor, and the primary path for
> >> HF signals is through the coil.

If 62.5% of the VHF current flows through the inductor ("coil"), and 37.5%
of the VHF current flows through the resistor, Tom, please explain how the
primary path for the VHF current is through the resistor?

ï¿½ Note to Tom Rauch---after we discuss the above analysis, I plan on
presenting a similar analysis for the 3-500Z parasitic suppressor that you
mentioned in your reply.

I have put up a new T-Hunt Web Page. Rather than write yet another introduction to T-Hunting, I start it off with some links to some known good T-Hunt pages, and then follow up with some stuff about the T-Helper and T-Helper Pro RDF projects. Hopefully by this time next year I will have a few new projects to write about as well.

http://www.quicksilver.com/~rbarris/

There is a link to the T-hunt section right there on the home page.

Hope you all like it. I previewed it on both Mac and Windows versions of Netscape 2.02/3.0 and everything looks OK here, but do let me know if you spot anything strange. I did get a couple reports of one animated GIF looking funny on Internet Explorer but OK on Netscape.

>adjustable blanking interval time and adjustable delay from the trigger?
>Has anyone tried this? What kind of results were had?

I tried it years ago with favorable results when I had a local single
phase arcing problem. Depending on where the arcing is actually
occuring in the substation, the arcing may be at a 360 Hz rate
corresponding to the voltage peaks of each of the three phases. Due to
voltage breakdown differences in the individual phases you can expect the
noise pulses not to be uniformily spaced in time. This means you might
need three (or six) individual phasing controls making for tricky adjustment.

I suspect a properly adjusted noise blanker followed by one of the modern
DSP noise cancellation filters might be a better way to go these
days but I don't have any experience with the DSP units as of yet.

>
It might work just fine, depending on the construction of the bridge.
The actual SWR values will probably be skewed somewhat, though. As a
relative indicator, you'll probably be able to get away with 6m on a
1-30 MHz designed unit, but not much higher.
As the frequency applied diverges from the design limits, the meter will
show progressively more error, up to the point where no useful
information is available. On some bridges, the sensor coil can actually
become an appreciable part of a wavelength. At that point, you're not
looking at the "same" point on the line anymore, and can't accurately
get a ratio of forward-reverse power.
Your best bet is to get a meter designed for the frequency you are
using, always making sure it is also designed for the characteristic
impedance of the line you are using, too.

From: robjohn@chesco.com
Message-ID: <56tues$gfo@news.chesco.com>
Source record: 100491

Howdy, Has anyone successfully used the newer high-beta MRF422's as replacements in a TS930/940. RF Parts price is $89/pr vs $169.95/pr for the low-beta versions. Kenwood gets about $190/pr for replacements. I'm in the process of trying to make this work and would appreciate any info on caveats to avoid re-inventing the wheel. Any comments or reflections would be appreciated.

Thanks much Greg K3EWZ robjohn@chesco.com

3073. Re: Syncronous Noise Blanker Idea

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-20 00:00:00 UTC
From: Peter Treybal <ptreybal@together.net>

Source record: 100554

I once thought of doing exactly this sort of thing to get rid of noise from those miserable phase-controoled light dimmers which are all over the area here. I'll bet it would work well for synchronous non-arcing noise sources. As a suggestion for the arcing situation, you could try looking at your line voltage with a scope synced to the line and see if you can spot glitches that are reasonably short that you could blank. I did that, and observed that the phase-controlled noise has a lot of time jitter, so I'd need to make some sort of "tracking" blanker. Duration of the damped sinusoids was about 5 microsec. Also, there were usually three or four sources! Sounds like good work for a DSP.

>Being relatively new to this NG, what is pre-and de-emphasis exactly? I know
>it's used in FM communications, but how and why?

The de-emphasis at the receiver end cancels pre-emphasis at the
transmitter. Pre-emphasis accentuates the higher frequencies in the
transmitted audio passband. The overall effect is a neutral transfer.

I understand the reason for this trickery is to attenuate high
frequency noise from the FM demodulator.

3075. CQ June'96 QRN Squasher, does it really work ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-20 00:00:00 UTC
From: Peter Shintani <shintani@tv.sony.co.jp>
Message-ID: <56tl7r$1c6@oskgw.osk.sony.co.jp>
Source record: 100556

Hi:
I had trouble finding the specified FET, so I used a similar 2SK125 fet.
The circuit worked but the frequency response was uneven and peaky.
It turned out that the RF choke I was using was self resonant at 1 MHz or
so. I searched and searched but I could not find a suitable RF choke that had
the specified 2.7 mH of inductance with a suitably high self resonance.
(I have feeling that a smallL would be ok.)
I gave up on the design. I had afew NEC upc1651 rf amp ic's. I replaced
the two gain stages with the upc's and used a simple hybrid combiner to
add the two signals.I have still to check the operation. But the
frequency response is now flat for the main antenna path up to
atleast 100 MHz, that is the measurement limit of my gain phase
analyzer. The Noise antenna path is -8 dB at 100 MHz.
I was wondering if anyone else had any luck with thie CQ QRN Squasher
as published and or knew of any mod's to fix or improve the performance.
I noticed that commercially available units have some sort of preselector
feature, it's lacking in the CQ ciruit, perhaps it is necessary ?
RSVP via email is appreciated

: as an fm demodulator (at least in theory). unless i'm missing
: something.

It's quite different, actually. The FM output (VCO input) would stay
constant with an AM signal -- nothing there. What you do is generate
an oscillation that is phase-locked to the AM signal, but won't go away
if the AM carrier momentarily fades, and you analog-multiply it with
the incoming signal. Result: Demodulated AM.

Why do this? (1) Better linearity than a diode. (2) It largely
counteracts "selective fading." Selective fading, as I understand it,
is what happens when the signal is momentarily added to a slightly
Doppler-shifted copy of itself (reflected off a moving layer of
the ionosphere). (Or maybe phase-shifted is enough; this isn't fresh
in my mind.) That's what makes the shortwave radio go mushy for a
few seconds every now and then. But if the PLL is well designed,
it won't change phase very fast; it will stay in phase with the
original carrier and the sound will be much better.

>help? 73 Ken W6GHV
>
Circuit board manufacturers use a super powerful base called "Tetra Etch"
to pepare PTFE boards for plated through holes and bonding of two boards.
It is Sodium Naphthenate. Before Tetra Etch was introduced a solution of
metallic Sodium in liquid ammonia was used (not the household cleaner, which
is ammonia gas dissolved in water, ammonia gas cooled to the temperature
where it liquifies. Not something you could do at home.)

PTFE is not easy to bond anything to. Most strip line circuits use a meltable
fluropolymer film to bond the layers. If you have a hydraulic press with
platens that can be heated to about 700 F, you can directly bond two layers
without the bond film.

Epoxy adhesives will give a reasonable bond, but it will depend on the
preparation of the surfaces to be bonded. Tetra Etch treatment before the
epoxy is highly recommended.

From: qlf@msg.ti.com
Message-ID: <56v4ph$i8t@sf18.dseg.ti.com>
Source record: 100572

PANEL METERS FOR SALE

I have for sale several 4-1/4"W X 4"H black-faced panel meters. These are perfect for a homebrewed linear amplifier or other suitable boatanchor. Available are:

0-5000 VDC (requires 5 MegOhm external multiplier resistor, not supplied)
0-1 ADC
0-1.5 ADC
0-25 mADC
0-50 mADC
0-150 mADC
0-500 mADC (2 each - one w/glass broken - easily replaceable)
0-350 VAC
Totalizer elapsed time meter (240 VAC, 60 Hz, shows 49,275.1 Hours)

These meters were manufactured by Westinghouse and were removed from the first FM broadcast transmitter (KOZY) in the state of South Dakota which went into service in the late 1940's or very early 50's and was only in service for two or three years.

Price, $10.00 each ($5.00 for the one with broken glass) plus shipping. $85.00 plus shipping for the lot.

Queston: Can anyone explain what the "ideal" grounding situation is for a ham
station. My shack is in a basement area. The tvi on cable is quite severe.

The antenna is a GAP vertical only 10 feet from the house. On 40 meters, when the amp is on (1 kw) it triggers a relay switch for the doorbell (also located in the basement shack area).

Reply: That's a pretty tall order! Your house wiring is so far into the antenna's near field that it is probably affecting antennna resonance--and functioning as part of the radiating system!

1. If there is ANY way you can move the antenna 1/4 -wave or so from the surrounding structures, (a.) it should work better and (b.) the RF level in your house will drop enormously (it's a cube-root relationship in the near field).

2. Put lots of ferrite sleeves on the coax before it enters the house. If the feed isn't totally decoupled from the antenna (which I doubt it is), it will (depending upon how much decoupling there actually is) radiate.

3. Run less power. If you can't move the antenna away, I don't really see how you can eliminate extremely strong RF fields from the interior of the house (unless you shield the whole building). Your only option, then, is to lower the field strength in the area by decreasing power.

A better ground system probably wont solve your problem--and it might even make it worse. Your house and its contents happen to be occupying the same space where the electric field generated by the antenna needs to be very strong in order to work. If you make the RF go away, your signal will probably go away with it.

> >130 MHz area. Will that be ok?
> >
> >73 Tom

OK, Tom, let's have a look: A typical anode VHF parasitic suppressor for a 3-500Z, operating at 3kV, uses a 70nH inductor. The suppressor resistor is typically 50 ohms. At 100MHz, the reactance of 70nH is 45 ohms. To find out how the current divides between the paralleled inductor and resistor, we can apply 1VRMS and calculate what happens. The current through the resistor is 1v/50 ohms = 20mA. The current through the inductor is 1v/45 ohms = 22mA. The total current is 20mA plus 22mA = 42mA. Thus, the resistor carries 20/42 = 0.476, or 47.6% of the total current. The inductor carries 22/42 = 52.4% of the total current.

Tom stated:
> >>I've said repeatedly the primary path
> >> for VHF and UHF signals is through the resistor, and the primary path for
> >> HF signals is through the coil.

Tom: If 52.4% of the current flows through the supressor inductor, and 47.6% of the current flows through the suppressor resistor, why have you 'said repeatedly' that the primary path for VHF current is through the suppressor resistor?

If a 3-500Z were operating at 4kV instead of 3kV, the suppressor inductor would have to be reduced to around 55nH to prevent the suppressor resistor from being crispy-crittered during 10m operation.** With a 55nH suppressor inductance, an even greater percentage of VHF current would pass through the VHF suppressor's inductor. (** see QST, March, 1989, page 25 "Calculating Power Dissipation in Parasitic-Suppressor resistors")
Since a substantive amount of VHF current flows through the suppressor inductor, the Q (XL/R) of the inductor should play a sizeable role in the overall VHF Q of a VHF parasitic suppressor. Is it logical that lower VHF Q would provide better VHF dampening? If this is true, then the effect of using a low VHF Q suppressor inductor should be readily observed on a dipmeter. With a high VHF Q (copper or silver) suppressor inductor, the observed VHF dip is sharp and deep. With a low VHF Q suppressor inductor,

the dip is broader and less deep. This is nothing new. Mr. F. E. Handy knew it 70 years ago. You can read what he wrote about VHF parasitic-suppressors in the 1926 and 1927 Editions of the ARRL's *Radio Amateurs Handbook*, Mr. Rauch.

> I will be off-net for two or three days.

Looking forward to your return in two or three days, Tom.

> BTW, Tom Brown keeps asking who my sources at Eimac were. I can not give

I do not sign blank cheques, Tom.

Will the real Mr. XXX please stand up and identify himself? Tom: Is Mr. XXX "they"? When I asked you for the names of "it's the entire staff" at Eimac, you were evasive. When I asked for the name of Mr. XXX, you wre evasive. Mr. Brown told me that you appeared to be evading the issue when he queried you about Mr. XXX via e-mail
The bogus Eimac e-mail address is suggestive of a deception
.....Something isn't quite right here, methinks.

> Anyone doubting Eimac's position can investigate things on their own. I
> wouldn't wish the kind of technical nonsense being argued here on anyone.

Nonsense--like assuming that the path for VHF current path is through the suppressor resistor instead of through both the resistor AND the inductor? IMO, any "amplifier expert" worth his salt would have calculated the VHF L/R current distribution before making such a statement.

> My opinion is anyone believing fantasies about 25 watt grids handling 500
> watts,

I did not state that a 25 watt grid handles 500 watts. I stated that 500 to 700 watts would probably be required to raise the 8877's grid structure to temperatures that boil gold.

VHF energy making tuning capacitors arc,

Certainly not in an AL-80's tuning capacitor, whose VHF resonances are far removed from the anode's VHF-resonance point, but tune-capacitor arcing occasionally happens in TL-922's and SB-220s when the factory-stock high VHF Q suppressors are used. .

VHF parasitics causing
> glass to melt,

During a telephone conversation on 3/28/91 with Jim Riach, Vectronics' design engineer, Raich told me that Chinese-made 3-500Z glass-envelopes had melted for no apparent reason. Mr. Raich works directly for Paul Rivnak,

the owner of Vectronics, Ltd. At the time they experienced the glass-envelope melting problem, Vectronics was building single 3-500Z LA30 amplifiers for AEA. If you would like to contact Vectronics, Tom, the address is: 31 Estate Drive, Scarborough, Ont., CANADA M1H 2Z2. We sent them Low VHF Q Suppressor Retrofit Kit s/n 2173. Subsequently, AEA ordered Low VHF Q Suppressor Retrofit Kits and bulk materials from us so that they could retrofit lower-Q suppressors into older LA30 amplifiers. We shipped the first such order on 10/29/91.

>Photons making tubes on standby arc over,

It is hard to believe, but I've talked to physicists and engineers about this conundrum, and cosmic radiation photons seems to be the collective best guess.
Ever wonder why lightning follows a zig-zag path instead of a straight line? Many folks have wondered about this because logic says that any arc should take place on the shortest distance between the two points--i.e., along a straight-line, right? However, some people* have proposed that high energy photons from cosmic background radiation speeds up electrons in atmospheric atoms along their paths of propagation. Accelerated electrons are more prone to escape from their normal orbits and become free current-carrying electons---provided that the voltage gradient is sufficient to liberate them. In other words, ionization takes place along the path that is most easily ionized, which is not necessarily a straight path.
Tom: If cosmic radiation can change the path of a lightning bolt, does it seem impossible that cosmic radiation could have some effect on an amplifier-tube?

I found that the penny feed for my 10GHz dish worked much better
when it was loaded with a small piece of teflon over the slot
radiator. I glued the teflon block to the brass waveguide by
lightly sanding the teflon to roughen it up and give epoxy something
to adhere to. This seems to have worked since the feed is 5 years
old and has gotten banged around alot. The teflon has never fallen
off. The feed is also waterproof as a result.

Yeah, the Mocom is older than the Micor. You can use them for repeater
duty, but they're pretty old, and their performance is markedly worse
than the Micor (which is getting pretty old itself). I wouldn't waste
my time on them (unless I had plenty of time to waste and no money to
get a more desirable radio).

Greetings!

E-LAB Digital Engineering, Inc. is pleased to make freely available our new
Electronics Internet Resource Directory!

This directory is a collection of many internet sites of use to
electronics builders, designers, and engineers. It is divided into
40 categories, with each category containing many hot-links to companies
and/ or web pages containing information on topics from Compilers to
Code Examples to Components Distributors.

The directory is available at http://www.netins.net/showcase/elab
You WILL want to set a bookmark!

We also invite you to check out our products, such as our new line of
integrated circuits for embedded design.

Thanks,

Todd Peterson

>inductor carries 22/42 = 52.4% of the total current. [snip]

Don't you think it wise to consider the phase angle of these currents. This ain't DC you know. Furthermore, these aren't isolated components tested in a measurement system, they're embedded in a system that includes other reactances and frequency dependent source and load impedances. So, their functional behavior is quite a bit more complicated that this "Ohm's law" analysis.

Most of the less expensive SWR meters that are the "trough line" type work up to 2 meters quite nice. These are the cheaper $19.95 CB Vanco and other brands. They're usually the 2.5 in wide 6 in long 2.5 in high box's that feed on each end straight through (the size is approx). Most of these type also do field strenght with a small screw hole at one end above the SO-239 (female chassis PL-259) jack for the externa whip.

The models with toroids are usually more frequency selective and the next step up from the above described with power/watt scales are not really accurate accross the usefull range.
But Hey! The SWR function is a keeper and the Power/watt readout can be calibrated to the 6 meter band. A good percentage of these meters are pretty close out of the box..
Good luck John, Look to the ARRL handbook on ways to calibrate it up on 50MHz.

You can "sort of" get Teflon to stick by the above method. But it isn't very strong. I've used contact cement when I just wanted a piece of it to hang on for a while.

I asked the local plastics man about glue for Teflon and nylon. He has been looking for a decent product for years. He told me that every one that has been on the market has not satisfied him.

Teflon is fairly easy to machine; depending on your needs if you have a fairly thick piece you can drill and tap it for screws.

Before buying a new one, give the following a try: Hook up a dummy load to the tuner, one that will present a nice 50 + j0 ohm impedance, and see what the meter thinks the SWR is. Then give it a 100 + j0 load, and 25 + j0 load. These should be 2:1. Etc. Probably they won't be right on, but before you throw that one out the window, repeat the experiment with 30 MHz! I use an MFJ-949D tuner for 6m though they're rated for only up to 30 MHz. The readings are off at 6m, and only slightly less off for 10m. If what you want the meter for is to see where the dip is, and not to know the precise value of the SWR, then even is the meter is quite off, it will still work.

Well, back in the old days, we had all these phase modulated radios,
and there's an inherent pre-emphasis in the phase modulation process.

So, to get a flat audio response (or something even close), you have
to have de-emphasis at the receiver end. Of course, there's an inherent
advantage with respect to high frequency noise reduction...

Who is "they"?
Mr. Rauch can't say .

Who is Mr. XXX with the phony e-mail address?
We can only guess.

On and on.

In an e-mail to me 4/5/96, Mr. Rauch said:

"If you are so sure of your theories, let's debate on Internet. We can go over your theories point by point in a non-personal debate."

for instance:
I asked Mr. Rauch: what is the frequency of the anode-circuit's resonance in the AL-80?
I asked Mr. Rauch: does the AL-1500 8877 amplifier (which Mr. Rauch designed) use a vhf parasitic suppressor?

Mr. Rauch appears not to have answered these seemingly-simple questions.
How can we go over theories point by point if one party is pointedly less than forthcoming?

THe "inherent advantage" was not something that came by accident.
Armstrong's FM _System_, that he developed and patented, based its
superior performance on preemphasis. We're talking about the wideband
commercial BCB FM, of course.

In article <56o32s$br7@mtinsc01-mgt.ops.worldnet.att.net>, <Unknown> says...

>The G.E. MASTR II and MASTR Executive II low band mobile radios are excellent donors
>for high power P.A.'s. Just make sure that the radio is a "high split" i.e. 42-50 mHz
> unit.
>
>Also, you'll have to pad down or otherwise reduce the power output of your exciter to
>a few hundred milliwatts as that is the drive level that these P.A.s require.
>Mail me if you need any other information.
>
>Steve, WB6TNL
><sigcom@juno.com>

I agree with Steve, the Mastr II and Exec II are good choices. The PA section comes right off the back of the radio, and one of the two relays you will need, as well as a low pass filter, is already there.

Another possibility is the PA section from an RCA TAC 300. The back of the radio, like the GEs, is a heatsink with the power amp, antenna relay and low pass filter. This amplifier uses an MRF 492, which can take the 5 watts from your radio and put out 60 watts or so. There are a couple of capacitor changes to be made; if you find some of these radios and need the information, let me know. I have converted several EXEC IIs and TAC 300s to 6, and they all worked great.

Keep your eyes open for amplifiers made by TPL for 30-50 MHz, which will do the same thing. I have used a couple of these for 6 meter amps. They put out 60 or 70 watts for 5 watts in. They are black "brick" type amps. I see alot of high band ones at hamfests, so make sure you get a low band model (the high band ones aren't bad for 2 meters).

3117. Conjugate matching & non-linear sources

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-21 00:00:00 UTC
From: jeffa@ix.netcom.com
Message-ID: <571o9c$pjm@dfw-ixnews5.ix.netcom.com>
Source record: 100503

It's been stated a number of times in different Usenet group threads that a Class C amp will deliver maximum power to a load when it is conjugately matched to that load. I've always puzzled over this statement, simply because a Class C amp is a non-linear device, and how does one conjugately match a linear load to a non-linear source? In an attempt to get a better handle on understanding the concept, I thought I'd try a little experiment. The results are interesting, and I'd like some comments as to how to interperet them.

Let's consider a simple circuit with a non-linear source resistance, and, to make things even simpler, let's consider it at DC. In particular, let's consider this circuit:

```
|\|
--------| |-------o----- Vout
| |/| |
| 1N4148 |
----- Rload
--- 1 VDC |
----- |
| |
| |
Gnd Gnd
```

As I vary Rload, at what resistance value is power dissipation maximized in the resistor, and do I have a conjugate match with the non-linear resistance represented by the diode at this point? (Admittedly, "conjugate" match at DC doesn't make much sense - there are no reactive components - let's just say, "Are the resistances matched?").

I used PSPICE to model the circuit and plotted power vs. Rload. Not surprisingly, there was a peak in resistor power, and this peak occured when Rload was about 18.6 ohms (Vout = 0.1855 v, I = 9.97 mA).

At this operating point the diode looks like an 81.7 ohm resistor. It's dissipating the same amount of power as a resistor of this value, it has the same voltage drop - for all intents and purposes, it *is* a resistor of 81.7 ohms.

Well, thought I, that's pretty conclusive. Maximum power does not necessarily mean conjugate match when the source in non-linear. After all, 81.7 ohms does not equal 18.6 ohms.

Unwilling to stop there, I thought I'd try a "load pull" test. This is a method to measure the source resistance of a generator by

varying the load resistance slightly and measuring the output voltage. From these values one can calculate the source resistance with the following equation:

Rs = (Vout1 - Vout2)/((Vout2/Rload2)-(Vout1/Rload1))

(See "Dynamic Resistance in RF Design," by William Sabin in the September '95 issue of QEX).

Choosing two resistance values that straddled my "optimal" value of 18.6 ohms, I got the following:

For Rload = 18.2 ohms, Vout = 0.1834 v
For Rload = 19.0 ohms, Vout = 0.1874 v

Plugging these into the formula above, and voila, the source resistance is...18.7 ohms! Pretty damn close to my optimal load resistance!

So now I have two values of source resistance. One directly measures to be 81.7 ohms, the other indirectly derived to be 18.7 ohms. If I rely on the load pull test alone, I'd say that I was conjugately matched. But I know that the diode at this operating point looks exactly like an 81.7 ohm resistor, and therefore we are not matched. In other words, I "measure" 81.7 ohms, but I "model" 18.6 ohms. Which interpretation is correct?

(As an interesting note, the load-pull test is measuring the "small signal" resistance of the device, and it is this resistance that it has modeled as the source resistance of my generator system. That is, at the optimal DC operating point (as found above), the slope of the diode's V-I curve is (roughly) 18.6 ohms, and it is this slope that the load-pull test has calculated. "Linearizing" non-linear devices through derivation of small-signal parameters is a common technique used to create small-signal models (such as the "hybrid-pi" model of a transistor). Such models are designed to be used when the signal levels are, well, small. Is such a method (and model) applicable to a large-signal non-linear device such as a class-C amp?)

Any opinions would be appreciated!

3120. Re: YIG oscillators home brew?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-21 00:00:00 UTC
From: dickrb@lsid.hp.com
Message-ID: <5720ck$ab5@hpcvsnz.cv.hp.com>
Source record: 100506

Hi - You will be hard-pressed to make your own YIG oscillator. There are many subtle things involved in building such a beast! For example:

- Obtaining a YIG sphere

- You will have to have some sort of physical structure to correctly position the sphere (X/Y/Z axis) in the magnetic field.

- Correct drive level to prevent 'squegging'-type oscillations.

- Designing a suitable magnetic structure.

- The completed device drifts terribly freq-wise unless you provide a reasonably stable thermal environment for the YIG and have chosen the best X/Y/Z position w/r/t thermal drift, squegging, and localized freq drop-outs.

These are just a few points that come to mind after many years of working with YIG structures. I've built 1000's of these devices years ago (designer and pdn-engr) and they do have many good features.

The only proper way to glue PTFE (Teflon) is to chemically "burn" the surface with one of the chemical mixtures sold for that purpose. These mixtures contain free sodium metal (or similar alkali metal) in solution and are very unstable and toxic (meaning dangerous to handle). Not recommended for amateurs.

The best way is to purchase PTFE that is already surface treated (it will have a dark brown appearance on the surface). Most commercial PTFE suppliers will be able to supply it at least in the thinner sheet material. Then you can glue it with any suitable "flexible" glue like contact adhesive. Some years ago I made a large number of electrical coils potted in polyurethane with a PTFE disk glued to one face by this method and they stood up very well.

This also explains why all PTFE self adhesive tape that is available has a dark brown appearance. Which brings up a point. If all you need is a thin layer of PTFE glued to a surface, self adhesive tapes are available in thickness up to at least 5 mil.

Well, maybe. One more test you should do. Put the meter in line
with a good dummy load, read forward and reverse. Now reverse the
connections to the meter and read forward and reverse again. If
the first forward reading doesn't match the second reverse reading,
and if the first reverse reading and the second forward reading
aren't very close to nil, the meter doesn't have enough directionality
to trust.

>John Mcleod N6RCD

I've been using a cheap Vanco $10 CB-type VSWR meter since the mid 1970s on all bands from 80m through 2m, and it works just fine. The "purists" will argue that the VSWR measurement is not accurate, and they're absolutely correct. But who cares? What does the meter reading actually matter? You adjust your antenna system for the minimum reflected power (whatever that may be) and that's it. You get it as low as it will go, and that's as low as it will go. The actual numbers don't matter. I've heard "newbies" on 2m complaining that they spent hours and hours trying to get the VSWR on their 2m antenna from 1.3:1 down to 1.2:1 and couldn't do it, and they were genuinely in a panic about it. Must've been former CBers. I know I felt that way when I made the transition from CB to ham back in the 1970s. Then I learned the truth about VSWR, and now I really don't worry. Anything below 2:1 is tolerable, and anything below 1.5:1 is down-right great!

Use the meter you have, and don't waste your money on another one, unless you're one of those anal-retentive types who's hooked on numbers.

>So, to get a flat audio response (or something even close), you have
>to have de-emphasis at the receiver end. Of course, there's an inherent
>advantage with respect to high frequency noise reduction...

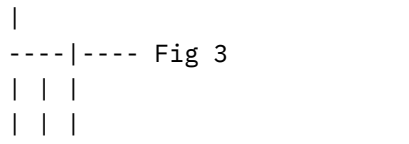
For a graphic demonstration of why pre-emphasis is necessary,
look at a spectrum analyzer display of a PM transmitter modulated
with pink noise. The close-in spectrum will look roughly like
this:

```
|
----|---- Fig 1
| | |
| | |
---------------------------
```

Now repeat the test with a FM transmitter *without* pre-emphasis.
It'll look like this:

```
|
/|\ Fig 2
/ | \
| | |
---------------------------
```

Put the pre-emphasis in and it'll look like this (hopefully):



Pre-emphasis equalizes the energy in the transmitted spectrum of
a FM system at all modulation frequencies. That maintains a constant
SNR at high and low modulation frequencies. A FM discriminator
has a response that's the inverse of figure 2, so if you don't
put de-emphasis in the receiver you'll get excessive high frequency
energy in the recovered modulation of a PM signal or a pre-emphasized
FM signal.

Peter:

I bread-boarded the circuit up and it seemed to work ok on the bench.
I also used FET's that I had on hand. For Q3 and Q2 I used a National
J309 For Q1, I used a 2N5245. (I would have used J309's for all 3, If
I'd had another.) My gain was a little peaky, maxing at 28dB at 1.2
MHz, then rolling off to about 15dB at 14 MHz, and rolling off more slowly
to about 6 db at 50 MHz. This is for the "Main antenna" input.
The gain on the sense antenna input varies as you fiddle with
the phase and balance controls, of course, but with both adjusted
for max gain, I got a peak of 25 dB at 0.5 MHz, rolling off rapidly
to only 5dB at 10 MHz, but then it was flat out to about
35 MHz or so. I really wanted to use the circuit on 6m,
where I have a chronic intermittent line noise problem, but the
gain might be too low there.

I just used a regular old 2.7mH molded choke for RFC1. As long as the
self-resonance is a parallel resonance, (it should be!) the choke should
have sufficent impedance to function properly. I just looked at mine
on the impedance analyzer. It had an self resonance at around 2 MHz, but
the impedance was still 3k ohms at 40 Mhz, which should still be adequate.

I'm not sure why you need a really flat response, although having a peak down in the BC band worries me; you'd be asking for overload problems with a local BC station. A preselector might not be a bad idea, especially if you were in such a situation.

I suspect that maybe DeMaw was thinking mostly about 160m operation. He mentions it a couple of times in the article. If you wanted to sacrifice gain at the low end, you could probably optimize the circuit for a bit more gain at the high end.

All that said, there's nothing wrong with using the MMIC's, though the noise figure might not be quite as good as a good JFET. (I don't have a data sheet for the 1651's but the 1653's have a NF of around 5dB.) I also wonder about their dynamic range relative to the JFETs.

Gee, you've inspired me to take my breadboard home this weekend and hook it up to a real antenna and radio, and see if it works.

Rob Frohne <frohro@wwc.edu> wrote:
: Hi,

: The other day I had an idea. The idea was for a syncronous noise
: blanker.

: So anyway, my idea is this: Assuming the noise is coming from arcing of a
: 60 Hz source, actually the same 60 Hz source I'm powering my radio on, and
: assuming it happens on peaks, then it will happen 120 times a second. Why
: not build a blanker that triggers on the 60 Hz line signal and that has an
: adjustable blanking interval time and adjustable delay from the trigger?

Hmmm...
This sounds like an interesting application for a circuit known as
a commutative filter. Little has been written about this, although Moto-
rola once had an application note on the subject. I have built a number
of these, usually using an NE565 PLL to lock onto a periodic signal. The
signal and all of it's harmonics are reconstructed by synchronously sampl-
ing the waveform in time. The phase relationship between the harmonics is
preserved, and a little post-filtering removes the switching transients
from the reconstructed waveform.

You would be able to determine the VSWR using a DIRECTIONAL COUPLER and some simple math. If you would like the plans, I can scan them and send them as an "image" file. Let me know what type of file you would like the plans in. (TGA,GIF etc...)
The plans are from The ARRL Antenna Book.

I am looking for an alternative to the commercial ~$450 DGPS receivers.
Does anyone have information to build a home-brew DGPS receiver to make
use of the 250 - 350 KHz marine radio DGPS beacons in the US and Canada?
Please email to griffin@ridgefield.sdr.slb.com.

Thanks,

Doug

I don't have an MD-1 but my Yaesu 990 has pin 2 and 5 as gnd return for control functions (ptt, up, dn, etc.) and pin 7 as gnd return for the audio from the mike. Pin 4 is "fast". The pin numbers are usually labeled on the front or back on plug and socket.

The 4 port hybrids would be a better solution than a 2 way divider w/ RG59. The output ports in a well designed 4 port hybrid will have 20 dB or better isolation- the result is that if one of your amps goes west, the other amp will not know it.
The capacitively coupled hybrids are easy to build and give you a degree of tuning capability if you make the 2 caps variable- they are also less lossy than Sage. Look through a Dec issue of an old HR and you'll see 4 or 5 hybrid articles listed, including capacitively coupled hybrids. I'm using a pair of these to combine 2 1296 amps.

One way to monitor lightning activity is to turn on an AM Broadcast
radio and set the dial to an unused frequency at the higher end of
the dial. Cheap and effective.

Probably the toughest value to measure is 1:1, and you can check this quickly and easily with a dummy load. Chances are that if it reads well at 1:1 it won't be badly off at other values.

A quadrature combiner (or any other passive circuit) does not insure 90 degree phase difference and equal magnitude of current in two loads of arbitrary impedance. The impedances of the elements of a phased array are equal only in a few special cases, and almost never if their currents are in quadrature. There's more information about this topic in Chapter 8 of the ARRL Antenna Book.

It depends on what aspect of lightning you're listening to. Could you be
thinking of whistlers? If so they're audible over a range of frequencies up
to around 10 kHz., and yes there are receivers for them.

True enough, 'it ain't DC', Wes, and the currents are not in phase, the exercise in question was to calculate the ratio of the current through the parallel R and L components. In doing this, I obviously ignored the intrinsic L in the resistor and I ignored the intrinsic R in the inductor. However, the answer is probably in the ballpark My point is that roughly half of the VHF current flows through the R and roughly half of the VHF current flows through the L. I believe it is hubristic to presume that the VHF current through either the suppressor R or L can be ignored with impunity, which has been Mr. Rauch's position for at least the past 6 years.

At DC, nichrome alloys are about 57 times more resistive than copper. To the best of my knowledge, there is no type of wire that has more VHF resistance, and produces a lower VHF-Q on a Boonton Q-Meter, than nickle-chromium-iron alloys.
The reason that high-resistance inductors produce a lower-Q VHF parasitic suppressor is that roughly half of the VHF current passes through a VHF suppressor's inductor.
All one needs to demonstrate this effect is a dipmeter and an HF amplifier. Low VHF-Q suppressors produce a shallower, broader VHF dip than the relatively higher VHF-Q suppressors that most amplifier manufacturers, including Ameritron, still use. A broader VHF dip means better VHF-dampening---which is what a VHF-suppressor is supposed to do. Mr. F. E. Handy realized this in 1926. I realized this in 1986.

. Even if we knew that the phase angle of the currents in L and R were, say for instance, 50 degrees apart at 100MHz, how would you use this information in designing a VHF parasitic-suppressor, Wes?

> >> This thread has outlived any usefulness.
> >>
> >> 73 Tom
>
> So it would seem.
>
Perhaps not. Mr Rauch indicated that he "will be off-net for two or three days."---or this debate may be near its end. However, in either case, an epilogue might be appropriate---provided that anyone is interested in the story behind the smoke and mirrors.

ï¿½ï¿½ EPILOGUE
Paul Pagel, N1FB, QST's Technical Correspondence editor related the following story to me:
Paul said that he comes to work at QST about a half hour early to unlock 225 Main Street. Shortly after "Parasitics Revisited" was published in the Sept. and Oct. 1990 issues of QST, as Paul opened up one morning, he could hear a telephone ringing in the back of the darkened building. He switched on the lights and started walking towards his desk in the back of the building. As Paul got closer and closer to his desk, the ringing became louder and louder. When he reached his desk, it was his telephone ringing. Paul said that this happened repeatedly over a period of weeks. The caller was always Mr. Tom Rauch, W8JI, from Ameritron, complaining about "Parasitics Revisited". . Paul said that Tom seemed to be especially concerned about the photograph of the burned bandswitch in "Parasitics Revisited" (page 33 in the October 1990 issue of QST). Tom was upset because owners of Ameritron amplifiers, whose bandswitches had burned up, saw the photo of the burned bandswitch on page 33 in QST and were apparently calling Ameritron to complain. Paul said that Tom blamed the burned bandswitches in Ameritron amplifiers on bad antennas, bad coax and bad operators. After many such telephone calls, Paul began to realize that he could not follow Mr. Rauch's technical logic, so Paul recommended that he telephone the author of the article, namely me, to resolve technical issues. .

Tom Rauch telephoned me. After identifying himself, he somewhat brusquely demanded to know if I was tape recording the telephone call. I answered no. Mr. Rauch was skeptical. After additional interrogation, he eventually became convinced that I was NOT recording the conversation, and we moved on to the matter at hand. Eventually, it became apparent that Mr. Rauch's concept of AC Circuit Analysis and my concept of AC Circuit Analysis are different. Mention VHF, and Mr. Rauch sees "coils" (inductors) as virtual open circuits. In other words, in Mr. Rauch's mind, VHF plus "coil" equals insignificant current flow, PERIOD. Next question. ....
OTOH, I believe that inductance and frequency should be entered into the appropriate AC Circuit Analysis formulae, and the results calculated.

I was amazed that QST Editor Mark Wilson never questioned Mr. Rauch's simplistic views on AC Circuit Analysis. See page 74 in the September, 1994 issue. Quoting Mr. Rauch:

"The coil's reactance increases with frequency, and at VHF it is plainly evident that the dominant component at VHF is the resistor, not the coil. Changing the coil has very little effect on overall Q."

Mr. Rauch is so sure that he is always right, he presented me with a 3-500Z L/R VHF suppressor current-division problem that he was certain would prove him right, and presumably bring me to my knees, technically-speaking. It backfired on Mr. Rauch.
I would think that one of our "recognized amplifier experts" would have taken the minute or so necessary to calculate the current distribution. If Tom Rauch had spent spent such a minute six years ago, he would have saved himself, QST, and yours truly much unpleasantness.

Not to disagree with Dick (who has indeed interacted with YIG devices a good deal and knows of the difficulties) but building a YIG oscillator on a ham budget/resources *is* possible.

In fact, Horst Aichmann, DL5KR, has done just that. I believe he used a packaged bi-polar as the active element and pretty much built it on a piece of copper clad with the coupling loop and YIG sphere pretty much "air wired".

I don't remember what magnet he used but I think if you are really set on building one, he could probably help.

->One way to monitor lightning activity

->Bart Mudde wrote:
->> Hello OM, who knows something about a receiver for lightning ?

Way back when I was going to college, I had a job with an outfit called Smythe Research in San Diego up by Montgomery Field. As I _vaguely_ remember, the best receiver for lightning was tuned SOMEWHERE around 50 kHz.

Again, that was a HELL of a long time ago. Anybody got any more recent information?

3149. Transformer For Power Supply

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-22 00:00:00 UTC
From: Dave Morrow <dave@cybergate.com>
Message-ID: <3295ED45.453A@cybergate.com>
Source record: 100443

I'm trying to build a 13.8v 20amp power supply and I'm having difficulty locating a transformer. This project may be more difficult than I thought. I'm looking for a 120v primary and 20v - 25v 10amp secondary or something close. Of the places I've called they don't carry it or they want $200.00 for it.

Any words of advise? Any ideas as to where to find a transformer at a cut rate price?

Help!!
Thanks, Dave

3150. Loop antenna theory?

I modeled the circuit using Pspice, and also could not see exactly how it would work under various conditions. It also displayed a fairly uneven and falling frequency response.

There is a 'noise bridge' type noise reduction unit published in William R. Nelson's "Interference Handbook". It uses only passive components. It also requires moving coil taps to tune it, which is not a very satisfactory solution.

Does anybody know of a published circuit other than these two? I would like to experiment. I don't want to cough up $175 for the ANC-4, since I don't need the transmit capability, and my needs are infrequent.

7.69 Hz is the self-resonant frequency of the Earth-Ionosphere channel. Lightning discharges anywhere on Earth will excite standing waves in this channel. Tesla discovered this in his Colorado experiments. As thunderstorms move toward or away from your location, the standing wave nodes will march across your location, peaking and fading according to the distance between you and the storm, and you can detect them with a suitable antenna and receiver.

Building a suitable receiver is not terribly hard. It is basically a high gain selective audio amplifier. Putting up an effective antenna may be much more challenging. Anything at all you can erect is going to be a *very* short (in terms of wavelength) voltage probe antenna. This will have an *extremely* high feedpoint impedance and will almost certainly need an integrated MOSFET to transform it down to something reasonable for the receiver. Protecting the gate of this MOSFET from static charges is going to be a very hard job, even the bias network is going to be difficult to build. You might be better off with a tube. Of course you could use a magnetic loop, but then the impedance would be extremely low, so you still have problems.

It is a marvel that Tesla detected anything. His receivers had no amplification, and even his huge antennas were still short in comparison to a wavelength at this frequency. But manmade electrical noise was a lot less in his day (excepting that he generated himself), so simple receivers performed better than they can today.

7.69 Hz borders on being below the audible range, so you need a chart recorder to monitor the output of your receiver. Or you could use a data acquisition card with your PC to log the signals. There's lots of interest to monitor throughout ELF, so a tunable receiver and a speaker should be part of your plans.

Moving up out of ELF to merely VLF simplifies your problems considerably, and there is still lightning energy to be detected there. In this region, whistlers come to the front as the interesting thing to monitor. As you move up in frequency above the audible range, you're going to have to add a detector (a simple diode envelope detector) to your TRF receiver in order

to hear anything. What you'll hear is the slope of the magnitude curve of the discharge energy. This can be interesting, but using a superhet with a product detector may prove more interesting yet because now you'll hear frequency shifts in the lightning discharge as well. At this point you may want to consider an upconverter to your HF rig, if it doesn't already cover VLF, instead of building a separate receiver.

Of course there is lightning energy to be detected all the way up into VHF, but the discharge has to be *very* much closer to your location to detect at VHF. This leads to a very useful monitor you can build. If you couple a MW AM receiver and a VHF AM receiver (a aircraft band scanner tuned to an unused channel will work) to a coincidence detector, you can get warnings for when storms are within a few hundred miles (crashes on the MW receiver), and when they are approaching your local area (simultaneous crashes on *both* the MW and VHF receiver). By monitoring both bands, you reduce the amount of false detections you get of approaching storms. We used this scheme to automatically start a backup generator when storms came into the local area.

Electrical noise is going to be the bane of your monitoring activities in any event. You're going to become familiar with every malfunctioning appliance within miles of your station, and grow to be on intimate terms with your local power company's EMI suppression engineers. Monitoring manmade EMI can be interesting in itself. You quickly learn the habits of your neighbors. (Most battery powered vibrators give off a distinctive ELF signal.)

If you can rough up the surface of the teflon a bit, regular contact
cement can be made to work. 'Course, it all depends upon how tightly
you need the bond to be... it works in most cases, but might not hold
if a LOT of stress was placed on it.

Hi Wes-

Are you saying that Tom was making a hasty (and incorrect) assumption when he said that he majority of any VHF current would go through the resistor rather than the suppressor coil? If that's what you are saying, then I agree. If not, then please explain how the difference in phase angle between the reactive path and the resistive path (the parallel resistor and inductor in the suppressor) would force the VHF current to flow through the higher impedance path rather than the lower.

I think I must be missing something..... (of course, it wouldn't be the first time THAT happened! <g>)

> Help!!
> Thanks, Dave

One approach you might try is to convert a 40A 5V linear supply to
13.8V. The basic approach is to rewire the transformer connections from
full wave rectifier using a center tapped transformer, to a full wave
bridge rectifier. This provides approximately 16V DC for the input to
the pass transistors. You then change the feedback voltage divider so
13.8V is divided down to the reference voltage. Finally replace all of
the electrolytic capacitors with higher voltage ones and lower
capacitance.
This generally results in a power supply whose pass bank has adequate
power dissipation capabilities and can handle 2X the operating current.
There may be some more details that I have forgotten but this should
give you the basic idea. The ones that I have converted so far have
started out as 10A 5V supplies. I generally start out by drawing up the
original schematic for the original supply and then working out the
modifications.
In this area used 5V supplies can frequently be found dirt cheap.
The principal disadvantage of this approach is the wasted .6V drop in
the additional diodes required for a bridge rectifier (12W at 20A)

Transformers that were intended for 5V linear supplies are frequently
available from mail order surplus dealers such as Alltronics in San
Jose CA and others for much more reasonable prices than you have found.

I hope this helps.

Motorola and GE used 807's in 30-50 MHz land mobile radios, many of which
were converted to 6M. They'll work. Don't know about the 12BY7A's.

Has anyone any idea if my ancient 807's are likely to produce more than heat from the anode on 6M ? Also I have some 12BY7A's here too which are often used as HF rig pre-final driver FT101Z etc. Are these likey to produce anything on 6M ?

Any info would be a help - its a junk box project and I'm trying to make a simple xtal TX without having to buy anything. I have some 4CX250B's but these are a bit over the top ...

I have a couple of good options for ya. Guess which one is serious?

1) TVI isn't a problem nowadays. The interference is better than the
programming.

2) Contact the Center for Disease Control and tell them you want to be a
human guinea-pig in a self-conducted radiation cancer test.

3) Connect a relay to the transmitter that disables the doorbell relay
while you're transmitting. Put a manual override in there and you can
use the doorbell relay for a CW monitor.

4) Put the vertical on the roof with a decent radial system.

5) Hot glue several fluorescent "halo" lightbulbs on the ceiling of the
shack. Visitors will be really impressed by your "light show". Only
charge your friends half price.

>commercial BCB FM, of course.

Pre-emphasis equalizes the energy in the transmitted spectrum of a direct FM signal so that it matches that of a PM signal (the most common way to do "FM" in the early days). That has the effect of improving SNR for high modulation frequencies (which otherwise would be worse than for low frequencies, see spectrograms I posted in another message). It doesn't give WBFM its superiority in gaussian noise over AM, however. One could add pre-emphasis to an AM signal as well, but wouldn't get the benefits of WBFM noise reduction. (What you'd get in that case would be *worse* low frequency baseband noise.)

The major advantage of WBFM is due to use of a modulation index in excess of 1. That yields the FM enhancement effect, which is really a crude form of spread spectrum. The signal energy is spread over a fairly wide bandwidth during transmission and collapsed back down to baseband during reception. This yields an improvement in baseband SNR in excess of the naive CNR. This is the same mechanism responsible for "coding gain" in a DS spread spectrum signal. The reason it works is that the signal energy is coherent, and adds when collapsed back down to baseband, but the noise is random and does not add when collapsed to baseband. Thus baseband S/N is better than the channel carrier to noise ratio. With AM, CNR and SNR are the same.

measures@mail.vcnet.com (R. L. Measures) writes:
>Mr. Rauch appears not to have answered these seemingly-simple questions.
>How can we go over theories point by point if one party is pointedly less
>than forthcoming?

You seem to feel it OK for you to not respond to questions, yet after I plainly posted I had to go off-line for two or three days you fire away with nonsense about me not replying. So far you've claimed:

1.) The grid dissipation of an 8877 is several hundred watts, never mind Eimac says 25 watts.

2.) The heating is by grid conductor resistance and not electron bombardment, never mind the grid's surface resistance would have to be hundreds of ohms or the grid current hundreds of amperes for this effect to occur.

3.) Photons make gas-LESS tubes on standby blow up. Never mind a special gas filled geiger muller tube only has fraction of a pico-ampere.

4.) Glass in Chinese 3-500Z's melts from parasitic current flow in what you call poor dissipation factor glass. Never mind the thermal lag of the glass or the electric field required.

5.) A capacitor can arc over from a parasitic but NOT HF energy. Never mind the reactance of the capacitor is very low at VHF but high at HF.

6.) A band switch can arc over from VHF parasitics. Never mind the low shunt reactance plate capacitor.

7.) A single point on a constant current characteristic curves can be used to calculate dissipation. Never mind the operating conditions indicated are off the charts.

8.) A relative harmonic level graph for a class C 4-65A can be applied to an 8875 as a direct percentage of harmonic even though it isn't even in percent.

9.) Adding a slightly resistive nichrome wire (how much Rich? Less than an few ohms?) in the primary path of HF current affects VHF Q greatly, when the VHF Q was already about unity at 100 MHz in the out of circuit "conventional suppressor" you describe.

Yet after all that very obvious technical rubbish you put out, you claim I am the one putting out the snow job, distorting facts, avoiding questions, and thinking customers are "drooling idiots".

I am supposed to answer you and spend hours correcting nonsensical claim after nonsensical claim, while you are free to avoid any question or spit out any response you choose. You, and in particular the magazine that gave you a platform to publish such obvious technical garbage, should be ashamed of what was done to people trying to learn. I think undoing the damage is impossible.

More time arguing with you is simply wasted time.

I did a longhand analysis of this circuit and could find no source of
phase shift, other than a 180 degree flop as zero amplitude was crossed
with either pot.

Later on, I breadboarded the phase circuit section up through the JFET,
and measured it on a Harris Vector voltmeter. It had, as theory indicated,
almost NO phase shift other than a 180 degree flop when zero is crossed.

QST sent me a photocopy of Bill Orr's letter. Mr. Orr claimed that there were 'numerous technical errors' in "Parasitics Revisited". Mr. Orr's allegation was discussed at a QST staff meeting. However, since Mr. Orr failed to specify even one error, the staffers at the meeting collectively agreed that Orr's letter was a "zero". (David Newkirk, WJ1Z-now W9VES)

> Harris, Rockwell, Siemens, GE, ETO, Ten Tec, Heathkit, Drake, Sanders,
> RCA, Ameritron, and all the other manufacturers aren't as knowlegeable as
> Rich. Who says this??? Rich.

No

Hmm....."and all the other manufacturers" too? Wow! I was not aware of this, Tom. Please provide us with a list.
Vern Baumgartner, W6HW, who worked as an engineer for Art Collins before Art sold out to Rockwell, told me that Collins used a nickle-chromium alloy inductor in the Collins Radio 30S-1 amplifier's VHF parasitic-suppressor.
A Hughes engineer told me that they use low VHF-Q parasitic-oscillation suppressors in a 100kW HF amplifier design.
I guess it's sorta like air-bags, Tom. Some people say they save lives. Other people say air-bags kill.

> Companies like those, and dozens of people who contacted QST to point out
> the errors in your articles, must just avoid your suggestions because they
> just don't understand theory or physics as well as Rich.

Big organizations don't always do the right thing, Tom. NASA launched Shuttle Mission 25 even though NASA had videotapes of 10 previous missions where fire could be seen coming through the o-rings on the booster rockets, adjacent to the main hydrogen tank, no less. In fact, NASA had previously fired the two safety engineers who were trying to get the leaky o-rings fixed before Mission 25 sent Christa McAuliffe and friends into the Atlantic Ocean at 200 knots plus.
Ford chose to save a few dollars per Pinto automobile on a gas-tank crash protector, even though Ford KNEW that Pintos turned into Molotov Cocktails in rear-end crash tests. More than two hundred people were cremated alive in Ford Pintos.

One of the alleged errors that was criticized in my article "The Nearly Perfect Amplifier" (QST, 9/94) was my assertion that R-C "equalizer" networks across silicon rectifiers could cause premature rectifier failure. 1200 words of space in the 9/94 QST was devoted to criticism of this. However, in the 1995 Edition of the Radio Amateur's Handbook, the author of the power supplies chapter says that R-C equalizer networks can cause premature rectifier failure---and he explains why.

ITU'S HOLIDAY SALE!
See our web page for more details
http://www.itutech.com

If you've ever wanted to get started with the Microchip PIC family of microcontrollers then now is the time! Our SPECIAL HOLIDAY packages are the perfect way to GET PIC'n! We've bundled our popular programmers
with Square One Electronics' Easy PIC'n Book and an electrically erasable
PIC16C84 microcontroller to get you started in the wonderful world of PIC
microcontrollers today.

****
Package #1

* PIC-1a Programmer (reg. $39 kit, reg. $59 Assembled/Tested)
* Easy PIC'n microcontroller book (reg. $29.95)
* PIC16C84 microcontroller (reg. $8)

GET PIC'n Pack #1 - All of the above for only $59 Kit, $79 Assembled!

****
Package #2

* Warp-3 Programmer (reg. $129 Assembled/Tested)
* Easy PIC'n microcontroller book (reg. $29.95)
* PIC16C84 microcontroller (reg. $8)

GET PIC'n Pack #2 - All of the above for only $149!

****
* Add our advanced development environment, CESSIM, to any of the above *
* packages for the special holiday price of only $49 (reg. $99)!
*
****

And don't forget our Caller ID to PC (RS-232) kit is still priced at only $39!

Please see our web page for more product information,
http://www.itutech.com

SPECIAL EXPIRES 12/31/96, SO ORDER TODAY!

ORDERING INFO

We accept Visa, MasterCard and American Express credit cards, personal checks and money orders, or COD orders (add $5). Please add $5 shipping
inside the US, $10 for airmail shipping outside the US. All products are sent UPS ground unless otherwise specified.

You may order via phone, fax, mail or on-line using our new SSL SECURE Web Order Form. Please see our web page for details.

I managed to get a good RF ground in a basement shack by drilling a hole right through the concrete floor under the bench. Drill at an angle so when you drive the rod it will clear the bench! I used two 8-ft power-company rods. Use one threaded connector as a sacrificial "hammering surface" and drive the first rod until the mushroomed-out connector is about floor level. Take it off, thread on the other and tighten the two rods together (use a pipe wrench!). Put the mushroom on the second rod and drive it in. Take off the mushroom (save it...Uou never know when...).

This way you can hook a very short piece of braid between the TX and mutha earth.

However, I suspect that your vertical so close to the house, and your running a gallon, is the major source of the problem!

3185. TVI & RF Grounding

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-23 00:00:00 UTC
From: don.phelps@infoway.com
Message-ID: <848788028@infoway.com>
Source record: 100394

Rick,

Seems to me that you could run a separate circuit of 230 and 115
for your station, and use TVI bypass capacitors on that circuit
in addition to the circuit for the TV and doorchime.

Then you could put a high pass filter on the cable TV, they are cheap.
You could also wrap the cable coax for a few turns through a
ferrite core.

Hopefully you have some sort of antenna tuner with good Q
feeding your antenna, and/or have a low pass filter.

Now about your question about your RF ground, I donn't think you
want to use anything that runs back into the house.
Combination of ground rod and ground radial wires under the vertical..

Before you do much work on that vertical, why don't you build
a reference dipole for 40 meters. Then compare the TVI between
the dipole and the vertical.

That should get you some improvement and better information,
without wasting any money, but only getting things every ham
would like to have.

I have operated a vertical on 40 meters about 10 feet away from
a TV with rabit ears, and curred all the TVI with the above steps
with 100 watts PEP.

Don,
N6MCE

In the January 1996 issue of QST an automatic ATU (the AT-11) is
described.

Has anybody built this, and if yes, how satisfied with it are you?

Thanks in advance,

Paul

Does anyone have any circuit diagrams for the
NE602AN? Could you please tell me a source for
good circuits using this device? Thank you. Rod, W5HVV

3190. synchronous noise blanker

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-23 00:00:00 UTC
From: jupiter@europa.com
Message-ID: <jupiter-2311962238380001@europa189.europa.com>
Source record: 100399

I once built one of these. It used an op amp as zero-crossing detector for AC line using ckt from Nat Semi Linear data book. Then two LM555's. First generated adjustable delay for controlling the second which connected to HDR blanker gate out of U. Rohde book on receivers.

It worked beautifully on light dimmer source.

However, if you have interference from multiple light dimmers, some on different AC phase, and others set for different dimming levels, you soon need 5-10 different noise blankers.

I scrapped the idea, as you can imagine.

3191. Want Plans for 10m or 6m Duplexers

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-23 00:00:00 UTC
From: "Ricky L.Ponder"
Message-ID: <578k3e$2fd@lana.zippo.com>
Source record: 100400

Hello, name here is Ricky. Does anyone out there have plans to build Duplexers for 10 or 6 meters. I would like to put a repeater together for either band and if I could build the duplexers also it would sure keep the cost down. I've talked on several 10m repeaters when the band was open that people said were running homemade duplexers, but have never been able to get any information on them. Any info. will be greatly appreciated.

3192. Band pass filter for 144MHz reqd?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-23 00:00:00 UTC
From: Steve C <Steve@mjrigby.demon.co.uk>
Message-ID: <wwdwPDAo2ylyEw9s@mjrigby.demon.co.uk>
Source record: 100401

Hi,

I want a low (nil) loss on passband, and good loss out of band, filter for 2m (144-145 will do)

I'd like it to be capable of passing full TX power (400W PEP), but at least 50W PEP if not.

WHat design do I ned to use ?

Will a cavity have a wide enough passband, and a low insertion loss (AND be flat in the passband)

Or am I looking at an interdigital rod type ?

I have the facililty to tune the passband response to make it flat etc, ie any insertion loss tests, and can sometimes do return loss tests (VSWR)

Lastly, I need to be able to make it fairly cheaply as its for an experiment.

Any ideas ??

>Designer?

Radio Designer won't teach you to design radios, but it is a useful
tool. It is limited, however, to linear small signal analysis, so
it won't directly simulate the behavior of oscillators or Class C
amplifiers. You can use it to model the passive LC networks used
in such circuits. PSpice is better if you need to model non-linear
behavior.

Two useful books are:

RF Circuit Design by Chris Bowick
(ISBN 0-672-21868-2)

Introduction to Radio Frequency Design by Wes Hayward
(ISBN 0-87259-492-0)

A possible source... Such a transformer may be located in an old (toasted other than xfmr) high power audio amp. Get to know local service centers dumpsters! Beware of one thing - Many *large* stores have ther POLICIES and won't let you have or even buy unclaimed/defective gear. For example, I was looking for a TV camera for ATV and went by MWard. Service had a kilobuk camcorder with a trashed tape basket/drive - I just wanted it for the "real time" video, but they acted a bit paranoid (wonder if they thought I was undercover "scrap police") and would not give or sell it to me. Had to destroy it, they said. A friend in the business for himself fiannly came across one. Good Luk! Woody

de Dave AA1A,
Shorted turns changes Q of network and wastes POWER.. If you are
running 50KW and think the autotransformer effect will cause
high enough voltages at the unshorted ends then by all means
short them out.. If not then don't waste power.. If you read
the difference with a bridge, you will probably come to above
conclusion.

From: A Redshirt <occupant@psyber.com>
Message-ID: <01bbd944$0ba84040$50c087cf@occupant.psyber.com>
Source record: 100478

Hello.

Any suggestions on what is available/where to find a software
package that I can use to replace the endless drawings I have
"created" on the back side of Safeway market bags et al over
the years?

I do not need the functionality of transferring the drawings to
four-sided PC board layouts, or anything as fancy as that;
I'm just looking for a way to clean up and file a lot of loose
sketches, and document some of junk I have "invented" (?!)
over the last thirty years or so.

I assume that the library of "gadgets" or "elements" would
be of some importance also. And I can relate to the terms
such as Condenser and Kilocycle.

I'd appreciate your comments...

Thanks

> with nonsense about me not replying. So far you've claimed:
>
> 1.) The grid dissipation of an 8877 is several hundred watts, never mind
> Eimac says 25 watts.

I estimated that it would probably take on the order of 500 to 700 watts to elevate the 8877 grid to a temperature that would boil gold, which is clearly what happened when one views a gold-sputtered 8877 grid through a microscope.

> 2.) The heating is by grid conductor resistance and not electron
> bombardment, never mind the grid's surface resistance would have to be
> hundreds of ohms or the grid current hundreds of amperes for this effect
> to occur.

You seem to be ignoring the fact that Eimac determined than an oscillation condition was the cause of gold-sputtering from the 8877's gold-plated grid.

> 3.) Photons make gas-LESS tubes on standby blow up. Never mind a special
> gas filled geiger muller tube only has fraction of a pico-ampere.

Tom: Do you believe that there are no gas atoms inside a vacuum tube?
Your opinions on photons seem to be somewhat at odds with the findings of physicist Robert Roussel-Dupre, Alex Gurevich of Moscow's Lebdedev Institute of Physics, Genady Milikh of the University of Maryland, and Tom Tunnell of EG&G Energy Measurements
Tom: What do you suppose causes high speed x-ray film to slowly fog up when it is parked in a lead-lined container?

> 4.) Glass in Chinese 3-500Z's melts from parasitic current flow in what
> you call poor dissipation factor glass. Never mind the thermal lag of the
> glass or the electric field required.

According to Jim Riach and Paul Rivnak (Vectronics, Ltd.), the glass envelopes of some Chinese-made (c.1990) 3-500Zs reportedly melted in small

areas a few cm away from the anode-stem, for no apparent reason. Mr. Raich reported this initially to QST-staffer Rus Healy, NJ2L, and Rus recommended that Mr. Raich contact me. {Rus Healy edited "Parasitics Revisited" in the 9/90 and 10/90 issues of QST. Rus also furnished the gold-sputter damaged 8874 that is shown in the QST photograph. Rus told me that the gold-sputtered 8874 was removed from an Alpha amplifier, whose electronic grid protection had dead-shorted.at the same time that the 8874 failed.)

> 5.) A capacitor can arc over from a parasitic but NOT HF energy. Never
> mind the reactance of the capacitor is very low at VHF but high at HF.

Tom: Do you all tuning capacitors have the same internal VHF resonances? I do not believe that this is the case. For instance, the tune capacitor in the AL80 apparently has no VHF resonances that are near the VHF anode-resonance in that amplifier. Thus, I am not surprised that I have never heard a report of tune capacitor arcing in the AL80. However, I do hear occasional reports of bandswitch contact arcing in the AL80, as well as bandswitch contact arcing in its cousin, the SB-1000---which Tom Rauch blames on bad antennas, bad coax and bad operators. OTOH, tune capacitor arcing is common in the SB-220 and the TL-922----but they use a DIFFERENT tuning capacitor, Tom.

> 6.) A band switch can arc over from VHF parasitics. Never mind the low
> shunt reactance plate capacitor.

I do not understand what you mean by "plate capacitor".
>
> 7.) A single point on a constant current characteristic curves can be used
> to calculate dissipation. Never mind the operating conditions indicated
> are off the charts.

You said that meter-indicated DC grid current should be used to calculate grid dissipation. I did this. An average DC grid current of 150mA in a 3CX800A7 is hardly equivalent to being "off the charts". The RMS voltage at the 50 ohm cathode is essentially the same as the RMS output voltage from the 50 ohm exciter---roughly 27V. 150mA multiplied by roughly 27V is roughly 4W. Tom: How did you arrive at 20W of grid dissipation? Do you believe that 20W is capable of elevating the grid to gold-boiling temperatures?

> 8.) A relative harmonic level graph for a class C 4-65A can be applied to
> an 8875 as a direct percentage of harmonic even though it isn't even in
> percent.

(Note: This item is from a discussion on the Topband reflector group) .... However, briefly, the "graph" (Figure 21 on page 35 in *Care and Feeding of PowerGrid Tubes*) does NOT indicate that it applies to a specific Class of amplifier operation. The point is this: you indicated that a Q of 5.9 was okay. Immediately under Figure 21 Eimac says:

"A resonant circuit with a loaded Q of 10 to 20 is usually considered optimum. A lower loaded Q will result in greater harmonic output." ...

... ...

Tom: Are you saying that Eimac is wrong, and that Qs substantively lower than 10 are good engineering practice?

> 9.) Adding a slightly resistive nichrome wire (how much Rich? Less than an
> few ohms?) in the primary path of HF current affects VHF Q greatly, when
> the VHF Q was already about unity at 100 MHz in the out of circuit
> "conventional suppressor" you describe.

"Slightly"?.....Nichrome has at least 50 times more resistance than copper or silver. Also, nichrome has a slight magnetic property, so it exhibits additional loss at VHF, especially when iron is added to the recipe. Why wouldn't an amplifier engineer utilize such a material for a circuit designed to dampen VHF oscillations? Mr. F. E. Handy wrote about it the 1926 Edition of the *Radio Amateur's Handbook*.

> Yet after all that very obvious technical rubbish you put out, you claim I
> am the one putting out the snow job, distorting facts, avoiding questions,
> and thinking customers are "drooling idiots".

I happen to be the person that some of such customers called after they called Ameritron. When one of Ameritron's customers knows that there was nothing wrong with his coax, antenna, or the way he tuned up an hour before the arc occured that burned up the bandswitch, what do you expect? // Kenwood used to tell owners of TL-922s that their bandswitches arced and burned up due to 'switching the bandswitch while transmitting at full power'. Yeah, right.

> I am supposed to answer you and spend hours correcting nonsensical claim
> after nonsensical claim, while you are free to avoid any question or spit
> out any response you choose. You, and in particular the magazine that gave
> you a platform to publish such obvious technical garbage, should be

Hi Rich,

Doesn't that current distribution indicate the Q is unity?? If I have a Q
of unity, how much lower can I make it? What is the RF resistance of the
thing nichrome wires, and what is the goal IN THE CIRCUIT?

Dick Ehrhorn owes me one. Last year Dick was the technical idiot
conspiring against you. This year it is me.

From Warren Bruene of Collins radio fame to Buzz Miklos of Siemens, from
Chazen and Brandon of Eimac to Orr, everyone disagrees with Rich Measures
just because they WANT to sell people bad ideas.

Harris, Rockwell, Siemens, GE, ETO, Ten Tec, Heathkit, Drake, Sanders,
RCA, Ameritron, and all the other manufacturers aren't as knowlegeable as
Rich. Who says this??? Rich.

Companies like those, and dozens of people who contacted QST to point out
the errors in your articles, must just avoid your suggestions because they
just don't understand theory or physics as well as Rich.

Discussing circuit theory or physics is a waste of time, because even
textbooks are part of the anti-Rich conspiracy.

73, Tom

>
> 1.) The grid dissipation of an 8877 is several hundred watts, never mind
> Eimac says 25 watts.

I estimated that it would probably take on the order of 500 to 700 watts to elevate the 8877 grid to a temperature that would boil gold, which is clearly what happened when one views a gold-sputtered 8877 grid through a microscope.

> 2.) The heating is by grid conductor resistance and not electron
> bombardment, never mind the grid's surface resistance would have to be
> hundreds of ohms or the grid current hundreds of amperes for this effect
> to occur.

You seem to be ignoring the fact that Eimac determined than an oscillation condition was the cause of gold-sputtering from the 8877's gold-plated grid.

> 3.) Photons make gas-LESS tubes on standby blow up. Never mind a special
> gas filled geiger muller tube only has fraction of a pico-ampere.

Tom: Do you believe that there are no gas atoms inside a vacuum tube?
Your opinions on photons seem to be somewhat at odds with the findings of physicist Robert Roussel-Dupre, Alex Gurevich of Moscow's Lebdedev Institute of Physics, Genady Milikh of the University of Maryland, and Tom Tunnell of EG&G Energy Measurements
Tom: What do you suppose causes high speed x-ray film to slowly fog up when it is parked in a lead-lined container?

> 4.) Glass in Chinese 3-500Z's melts from parasitic current flow in what
> you call poor dissipation factor glass. Never mind the thermal lag of the
> glass or the electric field required.

According to Jim Riach and Paul Rivnak (Vectronics, Ltd.), the glass envelopes of some Chinese-made (c.1990) 3-500Zs reportedly melted in small

areas a few cm away from the anode-stem, for no apparent reason. Mr. Raich reported this initially to QST-staffer Rus Healy, NJ2L, and Rus recommended that Mr. Raich contact me. {Rus Healy edited "Parasitics Revisited" in the 9/90 and 10/90 issues of QST. Rus also furnished the gold-sputter damaged 8874 that is shown in the QST photograph. Rus told me that the gold-sputtered 8874 was removed from an Alpha amplifier, whose electronic grid protection had dead-shorted.at the same time that the 8874 failed.)

> 5.) A capacitor can arc over from a parasitic but NOT HF energy. Never
> mind the reactance of the capacitor is very low at VHF but high at HF.

Tom: Do all tuning capacitors have the same internal VHF resonances? I don't think so. The tune capacitor in the AL80 apparently has no VHF resonances that are near the VHF anode-resonance in that amplifier. Thus, I am not surprised that I have never heard a report of tune capacitor arcing in the AL80. However, I do hear occasional reports of bandswitch contact arcing in the AL80, as well as bandswitch contact arcing in its cousin, the SB-1000---which Tom Rauch blames on bad antennas, bad coax and bad operators. OTOH, tune capacitor arcing is common in the SB-220 and the TL-922----but they use a DIFFERENT tuning capacitor, Tom.

> 6.) A band switch can arc over from VHF parasitics. Never mind the low
> shunt reactance plate capacitor.

I do not understand what you mean by "plate capacitor".
>
> 7.) A single point on a constant current characteristic curves can be used
> to calculate dissipation. Never mind the operating conditions indicated
> are off the charts.

You said that meter-indicated DC grid current should be used to calculate grid dissipation. I did this. An average DC grid current of 150mA in a 3CX800A7 is hardly equivalent to being "off the charts". The RMS voltage at the 50 ohm cathode is essentially the same as the RMS output voltage from the 50 ohm exciter---roughly 27V. 150mA multiplied by roughly 27V is roughly 4W. Tom: How did you arrive at 20W of grid dissipation? Do you believe that 20W is capable of elevating the grid to gold-boiling temperatures?

> 8.) A relative harmonic level graph for a class C 4-65A can be applied to
> an 8875 as a direct percentage of harmonic even though it isn't even in
> percent.

(Note: This item is from a discussion on the Topband-reflector group) .... However, briefly, the "graph" (Figure 21 on page 35 in *Care and Feeding of PowerGrid Tubes*) does NOT indicate that it applies to a specific Class of amplifier operation. The point is this: you indicated that a Q of 5.9 was okay. Immediately under Figure 21 Eimac says:

"A resonant circuit with a loaded Q of 10 to 20 is usually considered optimum. A lower loaded Q will result in greater harmonic output." ...
... ...

Tom: Are you saying that Eimac is wrong, and that Qs substantively lower
than 10 are good engineering practice?

> 9.) Adding a slightly resistive nichrome wire (how much Rich? Less than an
> few ohms?) in the primary path of HF current affects VHF Q greatly, when
> the VHF Q was already about unity at 100 MHz in the out of circuit
> "conventional suppressor" you describe.

"Slightly"?.....Nichrome has at least 50 times more resistance than
copper or silver. Also, nichrome has a slight magnetic property, so it
exhibits additional loss at VHF, especially when iron is added to the
recipe. Why wouldn't an amplifier engineer utilize such a material for a
circuit designed to dampen VHF oscillations? Mr. F. E. Handy wrote about
it the 1926 Edition of the *Radio Amateur's Handbook*.

> Yet after all that very obvious technical rubbish you put out, you claim I
> am the one putting out the snow job, distorting facts, avoiding questions,
> and thinking customers are "drooling idiots".

I happen to be the person that some of such customers called after they
called Ameritron. When one of Ameritron's customers knows that there was
nothing wrong with his coax, antenna, or the way he tuned up an hour before
the arc occured that burned up the bandswitch, what do you expect? //
Kenwood used to tell owners of TL-922s that their bandswitches arced and
burned up due to 'switching the bandswitch while transmitting at full
power'. Yeah, right.

Hi

A 20 amp 13.8 volts power supply only costs about $100.

You should use 20 volts for the supply if you can get one. The more
voltage
you drop increases the heatsink area needed. In your design you will need
more than a 20 amp transformer unless you never intend to draw 20 amps.
Rate the transformer at 20 amps while producing 20 volts. This is overkill
but
keeps you in a safe area.

There's another good reason to do it. Analog multiplying is the same as nonlinear mixing or heterodyning. When the PLL is in phase with the carrier and is heterodyned with it, the upper and lower sidebands combine in phase. Because any noise associated with the signal has random phase, it tends to cancel a little, providing better signal to noise over an envelope detector.

In article <measures-ya023180002211960639420001@news.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

>True enough, 'it ain't DC', Wes, and the currents are not in phase, the
>exercise in question was to calculate the ratio of the current through
the
>parallel R and L components. In doing this, I obviously ignored the
>intrinsic L in the resistor and I ignored the intrinsic R in the
inductor.

Rich, you seem to consider circuit design a collection of generic values.
You arbitrarily assigned a value of 50 ohms to the resistor, and .070 uH
to the inductor. The AL-80 series uses a 100 ohm resistor, not 50. The
inductance of later units was indeed reduced to ~85 nH, mainly due to
reduced grid lead and anode lengths, but the earlier models (the "A"
series) used about 120 nH. Early AL-80 series units had longer grid and
anode paths, requiring larger values of inductive reactance. The SB-220,
with its' long grid leads, required more inductance also in combination
with less resistance. The typical inductance required in these PA's varied
somewhat, but was typically in
the 100-200 nH range.

Your calculations are exact for the values "pulled from your hat", but the
actual shift in current varies with the actual supperssor.

A second factor enters the equation, and this is the critical area. Adding
nichrome to the primary HF path does almost NOTHING to system Q. I have no
idea what guage wire you use, but let's look at some typical suppressors
when 5 ohms of ESR is added to the inductor Here are the numbers:

With your suggested values of 70 nH and 50 ohms at 100 MHz.
Q = 1.14 (par equiv values (p eq) are 50r and 70 nH
with 5 ohm esr from nichrome.
Q = 1.0 (p eq) = 44.34r and 70.9 nH

With 70 nH and 100 ohms:
Q = 2.3
with 5 ohm esr nichrome
Q = 1.8 (p eq) = 79.7 r and 70.9 nH

With 150 nH and 50 ohms:
Q = 0.53
with 5 ohms esr nichrome
Q = .5 (p eq) 48.6r and 150.4 nH

(This is the typical 220 suppressor, it has almost a 2:1 current ration in
the suppressor, with resistor dominant)

With 150 nH and 100 ohms:
Q = 1.06
with 5 ohms esr nichrome
Q = 1.02 (p eq) 94.7r and 150.4 nH

In all cases, the slightest reduction in load resistance across the coil woul do much more than winding the coil out of a 5 ohms loss material. Of course this considers the non-nichrome coil to be lossless, so the actual reduction in Q would be less.

From this very small reduction in 100 MHz Q, Rich claims all ills of the PA are cured. No melted glass, no photons, no oscillations, no arcs.

Rich, please explain why you go through the bother of adding a nichrome coil when the Q reduction is so very slight? In almost ALL the cases above, removal of 5-10 ohms of parallel resistance would have changed Q the same amount or more.

>current flows through the L. I believe it is hubristic to presume that the
>VHF current through either the suppressor R or L can be ignored with
>impunity, which has been Mr. Rauch's position for at least the past 6
>years.

I believe it is foolish to change a whole suppressor, when a parallel resistance of several hundred ohms across the coil would accomplish the same Q reduction.

> At DC, nichrome alloys are about 57 times more resistive than copper. To
>the best of my knowledge, there is no type of wire that has more VHF
>resistance, and produces a lower VHF-Q on a Boonton Q-Meter, than
>nickle-chromium-iron alloys.

If you measured the coil WITHOUT the loading resistor, as I recall you saying, your measurement method was flawed. Add the loading resistor, and measure the CIRCUIT. You will find almost no measureable change in Q until you lower the Boonton's frequency to HF. If you send me a suppressor, I'll measure it on my HP or Wiltron, they go up over 1 GHz.

I think though we can safely conclude making the coil out of nichrome mainly lowers HF Q, NOT VHF Q.

> I would think that one of our "recognized amplifier experts" would have
>taken the minute or so necessary to calculate the current distribution. If
>Tom Rauch had spent spent such a minute six years ago, he would have saved
>himself, QST, and yours truly much unpleasantness.

I would have thought Mr. Measures would have known how to use a Q meter properly, and how to calculate Q in a circuit. That would have saved us all many hours of time listening to wild pie-in-the-sky theories about photons, melted glass, boiling gold in 500-700 watt 8877 grids (never mind Eimac says 25 watt) and parasitics.

You've paid too much attention to discrete values Rich, and not to the system. Nice try, but once again you argument falls apart.

BTW if any of my numbers are wrong, let me know. None of us are perfect, are we?

Rich recently posted the following:

>Big organizations don't always do the right thing, Tom. NASA launched
>Shuttle Mission 25 even though NASA had videotapes of 10 previous
>missions
>where fire could be seen coming through the o-rings on the booster
>rockets,
>adjacent to the main hydrogen tank, no less.

This isn't radio, but I also don't think it's true. I'm looking at a chart from Richard Feynman's account of the Challenger investigation and it shows only seven missions in which there was any O-ring incident and 17 in which there were none. The 7 incidents involved erosion of the O-ring, but not, so far as I know, fire shooting out the side of the rocket. Perhaps, a specific reference to Rich's source would be in order.

Greetings,

Can anybody recomend a good reference book on testing of receiver/transmitter performance. A lot of material seems scattered about in old Ham Radio magazines and ARRL handbooks. RF Design and RF & Microwaves sometimes talks about test but, I havent come across a book targeted for the RF test engineer types.

BTW: Someone who can place back issues Ham Radio on CD ROM today could make a bundle. Some of the best technical articles I have seen are in those moldy old pages.

The kind of testing I'm interested in would be noise figure/sensitivity, IP ,dynamic range, SINAD etc...

I guess I want to be a RF test engineer some day.....

Thanks for any ideas

I could do the calculations for the AL-80's 100 ohm suppressor R and 85nH suppressor L---if you provide the anode resonant frequency for the AL-80,
Tom..

Hi, I am having problems with a HP 8060C Synthisized Signal Generator
that has the 86633B Modulation System and 86603A RF Section 1-2600MHz.

If you have any manuals or possibly dead pieces for spare parts or any
suggestions could you please mail me.

Thanks,

Scott Sidener

. . . snipped . . .

When I first got started in this hobby, I also had severe TVI problems. This was with cable television which I had expected to be basically immune to such problems. I tried everything I could think of and everything suggested to me by other hams in the local area. I was in the process of surrounding an older VCR with a metal box that I had created as a shield when I discovered that the cable connectors were only hand tight. When I tightened them - loo and behold the TVI on that set went away. I then checked the other two TVs and guess what - they too had loose connectors. True - I use a good quality low pass filter at my end but when I tightened all the connectors at the TV end the TVI disappeared.

I built up the board using FAR circuit board. Used the NTE replacement
FETs DeMaw suggested from Mouser.

Didn't do much for my line noise (which is radiating into the antenna).
Was able to cancel the computer trash somewhat. Circuit badly needs a
preselector in front. My best solution was to just raise the antenna
higher. (Now what am I going to put in that box?)

Well said Dean.. I've been using the same thing since 1976.. Good ol Vanco.

But I have seen other VSWR meters that have limits on the their diodes such that at QRP I cannot calibrate the
meter to a point that I would feel comfortable measuring with.

and to get further out of hand-

there are three differences between lawyers and lab rats:

1) lawyers reproduce faster than rats
2)lawyers will do things that rats refuse to do
3) unlike rats, if you experiment on lawyers, the staff doesnt get
attached to them

3236. Kenwood 850SAT & Autoswitching antenna systems

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-24 00:00:00 UTC
From: wb1dsw@aol.com
Message-ID: <19961124191900.OAA24576@ladder01.news.aol.com>
Source record: 100423

I would like to find out if anyone has figured out how to have a Kenwood TS850SAT "drive" a remote antenna switch. I have a beam for 20-15-10 and a all-band wire. I want the Kenwood to "tell" the switch when it's on 20-15-10 and then I'd like it to "tell" the switch when it's on any other band (to select the wire).

It's my understanding that "data" appears SOMEWHERE coming out of the 850SAT. This data supposedly has the band information selected from either the VFO or the mem channel. I'd like to use this "data" to drive the switch. I haven't purchased the switch yet but I feel most of the popular (Unadilla, Ameritron, etc) commercial brands would do.

But, I suspect I'll be homebrewing an external interface to bring whatever "data" the Kenwood's putting out over to the relays (in the switch). But first I have to determine "Is there data" and "where the heck is it coming out and it'd be nice to know "what form is it being presented in". Don't tell me to call Kenwood - I burned up my life's savings last week on hold and got nowhere with them.

So, if you know something about this (or if you know someone who might know) please share your info with me. If you know someone at Kenwood, that'd be helpful too. Wouldn't it be terrific IF someone out there HAS ALREADY DONE THIS and could share that information with me!!!??

I thank you.

I include a cathode-resistor (Rc) in my low VHF-Q parasitic suppressor retrofit-kit for the SB-220. The reason that Rc works in the SB-220 is that that there are two VHF-resonant circuits---one in the cathode (input) circuit and one in the anode (output) circuit. The frequency of both resonances is roughly 110MHz---obviously not a good situation unless one is trying to build a 110MHz oscillator.
With average-gain 3-500Zs, putting a VHF-dampening device in either the input or output circuit may produce stability. However with above-average gain 3-500Zs, using a VHF-dampening device in both the input and in the output is indicated.

BTW, the SB-220's input-resonance at 110MHz is created by the length of the RG-58u coaxial-cable that Heath specified between the tuned-input bandswitch and the cathodes of the 3-500Zs.

What is the better way of balancing tubes such as 3-500Z units? Is is better to balance the standing current for a given bias (zero bias in the 3-500 units of course) or should the plate current be measured at a give RF drive for each tube? One measures the mu of the tube while the second approach measures the transconductance. Which is more practical for hams?

3243. Sherlock system -- Alternate Chip

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-24 00:00:00 UTC
From: Malcolm Mallette <mallettem@trader.com>
Message-ID: <3298E1F4.4997@trader.com>
Source record: 100430

After my article on the Sherlock transmitter fingerprint system appeared in September 1996 CQ/VHF, I received an e-mail to the effect that the A/D chip used in the hardware, the MAX150 , had been backordered.

Another e-mail suggested I try the National Semiconducter ADC 0820 as a replacement.

The national Semiconducter ADC0820 can be used in place of the MAX150 with no adverse affect.

However, a minor change in the circuit board must be made.

On the Far Circuits board, disconnect pin 12 on the A/D chip socket (the one for the MAX150) from pin 19 on the same socket by breaking the trace. Leave pin 12 connected to the two caps to ground. Connect a 1.5 K resistor from pin 12 to ground and another 1.5 K resistor from pin 12 to regulated 5 volts + .

The MAX150 has a 1.5 V+ reference voltage out available on pin 19. The ADC0820 has no reference voltage out. THe change supplies from 2 volts to 2.5 volts as a reference voltage to pin 12 of the ADC 0820 That pin is the reference voltage in on both chips.

FAQ about Sherlock:

How can a get a schematic? If you are outside of the U.S., send me an e-mail.. If you are in the US (or Canada) find a copy of Sept 1996 CQ/VHF.

Where is the Sherlock software available: ftp.hcares.gen.in.us also should be in the
oak.oakland.edu website through the Boston Radio Club subpage.

Why use this hardware plus software instead of the program that uses a sound card:

1. You do not have a soundcard or the other program does not work with your
soundcard.

2. You like to build.

Is the software free? Yes.

Will you give me the source code? No.

What does it take to run the software? A 486 DX 33 minimum PC clone with a parallel port of any type. (LPT1) And with VGA

Will the system always be able to distinguish between transmitters of the same make and model? Read the article.

Are Circuit boards available? Yes FAR Circuits, 18N640 Field Court, DUndee, IL 1900t 847-576-3540.

Should I start sending e-mail to you before I have read the article? No.

Can I build it without the circuit board? Yes. Is it easier to use the board? Yes.

How much does the hardware cost? About $65 with case using the MAX 150 About $50 using the ADC0820. This is more or less what you have on hand.

Hi,
Name here is Gerry (WD4BIS) and I have been writing a column for our club newsletter called "New Ham Partner". With the influx of No Code Technicians on the repeater, asking the same kinds of questions I asked 20 years ago, I have been trying to answer them.
Some of the articles are technical, some of them are general information, but they all address subjects that our new friends are struggling with.

I have set up a web page for these articles. On this page, I will place the columns I have already published in past issues of our newsletter. Doing this on a web page has advantages, the big one being that the articles wont expire in a newsgroup, I can edit old ones or add new columns as write them, and I wont have to send re-posts.

The Cost... I will ask that you do not edit the articles, and use my by-line. If you use them, send me an E-mail and let me know when and where. If you have a spare stamp mail me a copy of your newsletter to the address on the page.

Where... http://web2.airmail.net/gerryc/newham.html

Please bear in mind this site is still under construction and not all of them are there yet, but they soon will be. (I have Thanksgiving week off)

73's

Gerry Crenshaw

I understand the confusion, Filip. There has been plenty of smoke and mirrors in this debate, and I suspect there will be more. Briefly---The roots of the debate date from 1926, when Mr. F. E. Handy said on page 72 in the *Radio Amateur's Handbook*:

"The combination of both resistance and inductance is very effective in limiting parasitic oscillations to a negligible value of current."

In other words, Mr. Handy found that VHF parasitic-oscillation suppressors performed measurably better when the suppressor's inductor (L) was made from resistance wire instead of copper wire. Nichrome has the highest volume-resistivity among resistance wire alloys, but it is not easily-soldered and is not commonly available..
After a few years, Handy's observation was somehow left out of the Handbook. After WW2, people apparently forgot what Mr. Handy wrote in 1926 and 1927, and people started making suppressors out of whatever was handy and easily soldered---i.e., copper. Some folks even started silver-plating suppressor inductors, evidently for cosmetic reasons. In the 1940's and 1950's, it didn't matter much what the suppressor L was made from because large amplifier tubes did not exhibit very much VHF gain. With modern, high-gain amplifier tubes, VHF suppressors with a high VHF-dampening ability seem to be indicated. High VHF-dampening means low VHF Q.

The difference between VHF suppressor inductors made from resistance wire, and those made from copper or silver-plated material, can easily be compared with a dipmeter. The first time I made this comparison was in 1986. With a copper suppressor inductor, the VHF dip was sharp and deep. With a nichrome suppressor inductor, the VHF dip was broad and shallow. Subsequent tests with a Boonton Q meter showed a substantive difference in VHF Q between otherwise-similar inductors made from copper and those made from nichrome. Additional tests with other alloys demonstrated that if a small percentage of iron was added to the nichrome recipe, an even lower VHF Q, and better VHF dampening resulted.
My findings were published in the October 1988 issue of QST magazine. The reader response was startling. During the next ten months, I received around 1200 telephone calls and letters from readers. I had to hire a helper to keep up with the mail.
Other articles I wrote about VHF parasitic oscillation were published in the March 1989, September 1990, October 1990, and the January, 1994 issues of QST magazine. The January 1994 article was written at the request of QST magazine. However, the January, 1994 article reportedly irritated some amplifier manufacturers, who still use high VHF-Q parasitic suppressors, who advertise in QST. (see QST, Sept., 1994, page 71)

For at least the past 6 years, Mr. Rauch has stentorianly asserted that essentially no VHF current flows through the L, virtually all VHF current flows through the R, and virtually all HF current flows through the L. Mr. Rauch believes that the suppressor L should be made from copper.

I contend that since roughly half of the VHF current flows through the L, a resistive conductor offers a VHF-dampening advantage. Dipmeter-tests with such a VHF-suppressor installed in various amplifiers demonstrates that with a nichrome L, the VHF dip is broad and shallow.

Now that Mr. Rauch has discovered that his oft-repeated assertion of the past 6 years is somewhat lacking in technical accuracy, he seems to want to talk about ANYTHING BUT the VHF current distribution between a suppressor's L and R. On and on, round and round. Apparently, "recognized amplifier experts" have a public image to defend at any cost---even though it's beginning to look like "The combination of both resistance and inductance is very effective in limiting parasitic oscillations to a negligible value of current."

Our PR-Internet link had some problems (hardware & software made in USA) so
I am bit late on interesting QRO tread. While preparing for CQ WW CW contest,
I survived 3600V shock thru both hands and combined with a recent light fire
under the bonet of my Chrysler LeBaron at petrol station, I live 4-th life now!
Gentleman 50 miles from Hollywood was asking while I did so brute test with my
SB-220 shorting the antenna. Well, I was convinced RF voltage can't go beyond
2 x DC and I went to the worst case situstion (is it scenario in South CA?).
However, I had many close situations in real life with intermittent antenna
problems, loading capacitor shorts, disconected coax cable shields etc...
AG6K math in calculating R/L current percentages on straight sum is WRONG!
Supressor inductance on VHF would affect oscilations by changing the phase
angle and not solely by reactance value.
I am sure KE4ZV supports KISS approach and if we can explain arcing with simple
model of light load on working frequency, lets refrain from mumbo-jumbo of UFO
effects in a good tradition of an engineering practice. Catastrophic failures
are beyond a reasonable price/performance design and are usually covered by
insurance or guarantee.

From: tgale@xs4all.nl ()
Subject: Valves/Tubes Web Page
Date sent: 14 Nov 1996 17:36:32 GMT
Organization: XS4ALL, networking for the masses

Good-day fellow radio enthusiasts. This is just a quick note to let
you know that I have started to set up a Web page with some valve/tube
information which I hope will be of help to those interested in restoring,
repairing or using valve/tube - based equipment. I have had a few positive
reactions to my first effort, but of course I welcome any good suggestions
and constructive criticism in order to improve the page, which I started
following a reply I was able to post to someone elses posted query.

The page should be accessible at: <http://www.xs4all.nl/~tgale/valves.html>

I find that most discussion in respect of this subject can be found
on the newsgroup <news:rec.antiques.radio+phono> but I thought I would
post this note to a couple of other groups where people might be
interested as well.

Regards, and 73's, F.C. Trevor Gale, G8GFH (resident in The Netherlands).

Balancing the zero signal anode current ('ZSAC) is probably more important
because if you don't have at least 70mA of ZSAC per anode, linearity will
suffer. However, if more than 100mA of ZSAC is used, heat becomes a
concern. As long as the ZSAC in one tube is at least 70mA and the ZSAC in
the other tube is less than 100mA, there should be no problem.

>
While it is true that relatively high currents circulate in the shorted
turns at settings of roughly 80% to 95% of Lmax, the alternative is far
more consequential--i.e., arcing at the unshorted end when settings of 5%
to 20% of Lmax are used. My own preference is to short the unused turns
with 1uH of L air-wound from #12 solid copper wire. This prevents the
tesla coil v buildup, and it limits the current that circulates in the
shorted turns.

Is this the right question?

If you have a receive problem, the filter doesn't need to be in the transmit path at all.

Any close-in filtering of a transmitter signal should be done at low level, in the exciter. With most commercial 2m transceivers you can fairly safely assume that close-in spurious products within a few MHz will be well suppressed (unless there's a fault).

The PA will contribute only intermodulation distortion (which is too close-in to be filtered) and harmonics, which are well separated from the output frequency and can be removed by a lowpass filter or even a multiple-notch filter.

Therefore there's absolutely no point in putting a large, difficult and expensive narrowband filter after the power amplifier.

>Lastly, I need to be able to make it fairly cheaply as its for an
>experiment.
>
Very cheap and effective harmonic notch filters cut from ordinary coax were described by G4SWX in RadCom about a year ago.

If this is a breakthrough problem, you can probably have your station officially inspected and your equipment checked by the Radio Investigation Service at no charge - e-mail me for details.

If my memory serves me right, the 10 missions out 24 figure was reported by NBC news. Even if there were only five previous incidents of shuttle booster rocket o-ring leaks, in my opinion it would have been a good idea to get the o-ring problem fixed, instead of firing the two people who were trying to get it fixed. Of course, if Dave and Tom have a different opinion, I support your right to that opinion. .

> Hi Dave,
>
> Perhaps Rich is preparing us for the revelation that the O ring failure
> was due to a parasitic oscillation, or perhaps photons from a solar flare
> caused the failure.

Tom pooh-poohs the importance of photon bombardment. NASA does not seem to share Tom's opinion. During a solar flare, photon radiation places astronauts at risk. As I recall, NASA does not lauch the shuttle during periods of intense solar activity. During a period of high solar activity about 170 years ago, photon bombardment of Earth created a continuous path of ionized gasses (a.k.a. arc) in the ionesphere between the northern and southern hemispheres. The path of ionization was reportedly seen by inhabitants of equatorial regions. The current flow in the arc has been estimated at 1000 amperes.

> Other than that, I'm having a hard time understanding what this has to do

The point is simply that big organizations do not always do the right thing. Did Ford really have "a better idea" when it knowing produced its family crematorium on wheels--i.e., the Ford Pinto?
According to a Ford internal memorandum, Ford executives assumed that it would cost less to settle the wrongful death lawsuits than to incorporate a gas tank protection member into the Pinto's frame. Were the Ford executives right or wrong, Tom? and Dave?

Tom:
ï¿½ Who is Mr. XXX? Why does he list an bogus Eimac e-mail address?.
ï¿½ Who are/is "they"?.
ï¿½ What are names of the people at Eimac, to whom you refer to as "it's the entire staff", who allegedly say that Mr. Foote and I are wrong about gold-sputtering being caused by an oscillation condition?
ï¿½ Does the AL-1500 8877 amplifier, which you designed, use a VHF parasitic oscillation suppressor?
ï¿½ What is the frequency of the anode-resonance in the Ameritron AL-80...amplifier ?
---

I go along with that completely. It is NOT a good idea to float the unused
turns. Unwanted series resonances cause much more problem than the shorted
turns. Flux leakage is so high in a conventional roller (the length is
often well over twice the diameter and turn to turn spacing can be wide)
that circulating currents are a minor problem. The idea of using a
reactive path seems to be a good one.

>Jesse , W6KKT (50 miles from L.A.)

Rich's math is OK, as far as he went. The values he selected were at the extreme low end of reactance, but are realistic in a 3-500Z with short grid and anode leads. The important parameter is the equivilent series reactance of the anode system, and that can be calculated quite easily.

I already calculated and posted the equivilent parallel circuit values of the suppressors Rich described, as well as some other more typical values. The change in VHF Q, when a lossless coil was replaced with a 5 ohms ESR coil, was almost nil. When those values are translated to the series equivilent, that circuit is placed in the anode path, you can calculate the system Q.

There are several ways to do this with either scientific approach or the Edisonian (cut and try) approach. This would be a good topic for an article, because too much of this stuff has become "do it this way" rules of thumb or folklore. Just like the myth tank Q needs to be 12, or the PA will not operate properly.

WB1DSW de KC5NG bt

Okay... I've done something SIMILAR that might help get you going in the right direction. MANY years ago, I had a Kenwood TS-430S, which had an output port for controlling a matching outboard antenna matching unit. The data was BCD (binary coded decimal) output. I used a BCD-to-decimal decoder chip (4-to-10 line decoder) and some open-collector transistor outputs to drive small reed relays to select taps on a mobile HF antenna loading coil. I never built the final circuit (sold the rig) but I did prototype it and it worked.

I would be willing to bet that similar info is output by your Kenwood. You might be able to do the same kind of thing. Check your rig manual

carefully, and perhaps check the service manual.

Good luck!

Gain-variation has nothing to do with feedback capacitance. Perhaps this will decrease your level puzzlement, Tom: The SB-220 has a VHF resonance in the input and a VHF resoance in the output. Both resonances happen to be around 110MHz. Approximately 0.2pF of capacitance exists between the input and the output. At 110MHz, 0.2pF has 8000 ohms of reactance. I believe that occasional oscillations at 110MHz can occur in the SB-220. The TL-922 has a similar problem at 140MHz, for the same reason. // According to the notes from our telephone conversation in 1990, you stated that you had worked on over 400 SB-220s, and that many of them had VHF parasitic-oscillation damage. Are you now saying that VLF is what you meant to say?

> The worse engineering mistake in the SB-220 was the inclusion of chokes

3265. Inexpensive but reliable frequency counter?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-25 00:00:00 UTC
From: OSTERTAGK@SNYCORVA.CORTLAND.EDU
Message-ID: <01IC9LIMC5N000LOR1@SNYCORVA.CORTLAND.EDU>
Source record: 100357

I'm a new ham and a would-be electronics experimenter (no technical background). One item I would like to own is a frequency counter, but I don't feel I can justify $300-$400 for a bench model. So I have been looking around for a kit or some plans to build one myself. There's one in the latest ARRL Handbook (6-digit, 50MHz) which can be bought as a kit for $79 from Radio Adventures. I also found two plans in Popular Electronics, a 25MHz 4-digit model in the Feb 1995 issue and a 50MHz model in the Nov 1994 issue.

Does anyone have direct experience with any of the above? Or maybe someone can offer an alternative? For instance, might it be better for me to buy one of those $200 radio frequency counters made by Startek or MFJ?

I just want one to help me play around with RF circuits, for the fun and education.

-Thanks,

Keith Ostertag, N3KXZ

3266. Amp help w/ 304tl

Message-ID: <01bbdb17$ffcbd5e0$LocalHost@ks>
Source record: 100358

Hi, I am looking for some help building an amplifier using a 304tl
I already have a 3kv supply for the plate supply. I have the specs on
the tube from Eimac, they are
DC Plate 3000v
DC Grid -400v
Plate Current 500ma
DC Grid Current 80ma

and so on

I have numerous questions, like , what would be a good circuit for this
tube?
Grounded Grid? What about an input circuit? What class would this be (A,
AB1, AB2)?
I saw somewhere the formula for figuring plate load, but can't remember
where.
I see alot of talk about parasitic suppressers, what would be the best
circuit for this?
I already have the basic hardware stuff started, I need some help on the
finer things!
Any schematics, component values, comments or what ever would be of great
help.
I know very little about designing amplifiers and any help would be
appreciated.
I also have a 3-400z amperex with socket, would this be a better tube for
this project?
anyone have the specs on this tube?

the Eimac SK-1306 chimney is made from fiberglass. It is about 7 inches in
diameter. You can buy one from Richardson Electronics in Chicago. They
are not all that expensive. // I have a quantity of Eimac long-finger
stock for afixing an anode HF contactor to the top a fiberglas chimney. If
you need some, say so. Such an arrangement results in much less L in the
neutralization circuitry. You can find an illustration of this techniqueon
the Web. The URL is

Vectronics built LA30 amplifiers for AEA. The field service was done by AEA---and, in November of 1991, AEA began retrofitting low VHF-Q parasitic suppressors into LA30 amplifiers that were returned because of parasitic-related damage. I have the sales records if you would like to see them, Mr. Rauch. Mr. Al Chandler was the person I delt with at AEA. As i recall, Vectronics recommended that Chandler contact me about retrofitting lower Q suppressors into LA30 amplifiers that were returned for service. .

Tom: who said that low Q suppressors were removed from Vectronics' amplifiers within several months of the initial test? I provided the names of the people I spoke with at Vectronics: engineer Jim Riach and owner Paul Rivnak. Who did you talk to at Vectronics?

It seems a bit curious that you would be skeptical about the glass envelope melting problem at Vectronics. I spoke to both the owner and the engineer about this problem, as well as to Rus Healy at QST. It also seems a bit curious that Raich and Rivnak would conclude that higher VHF-Q suppressors were better than lower VHF-Q suppressors if they recommended that AEA contact me about retrofitting lower VHF-Q suppressors into LA30s that were already in the field.

Tom: Have you posted your mathematical solution to the following, yet?

Tom: Are you suggesting that the primary path of VHF current is through the paralleled 50 ohm resistor? If you maintain that most of the VHF current passes through the 50 ohm resistor, Tom, please show us the mathematical solution that led you to your conclusion.

Rich recently posted the following:

>Big organizations don't always do the right thing, Tom. NASA launched
>Shuttle Mission 25 even though NASA had videotapes of 10 previous
>missions
>where fire could be seen coming through the o-rings on the booster
>rockets,
>adjacent to the main hydrogen tank, no less.

This isn't radio, but I also don't think it's true. I'm looking at a chart from Richard Feynman's account of the Challenger investigation and it shows only seven missions in which there was any O-ring incident and 17 in which there were none. The 7 incidents involved erosion of the O-ring, but not, so far as I know, fire shooting out the side of the rocket. Perhaps, a specific reference to Rich's source would be in order.

Dave KE9ED

>>

Hi Dave,

Perhaps Rich is preparing us for the revelation that the O ring failure was due to a parasitic oscillation, or perhaps photons from a solar flare caused the failure.

Other than that, I'm having a hard time understanding what this has to do with all his wild theories and claims about parasitics.

>output is indicated.

This comment puzzles me Rich.

You attribute a wide gain variation to tube differences, indicting it is
an input to output feedback loop.

The worse engineering mistake in the SB-220 was the inclusion of chokes
in paralle with capacitors from the grids to ground in the SB-220. It
makes that PA subject to VLF parasitics, and destroys gain flatness. It
makes the tubes less stable at VHF also. The single most important mod to
an SB-220 is to ground the grids right at the tube pins with very very
short leads.

You attribute problems to the gain of tubes. The gain of a grounded grid
PA, due to fact the input circuit is in series with the output RF path, is
determined by the ratio of cathode driving to anode output impedance.

In thousands of tubes of all types, I see very little gain difference.
There are even reject limits, for example 3CX1200A7's with as little as
.5 dB gain difference are rejected. That amounts to one tube in every few
hundred.

If there was a 3 dB gain difference, it would also show up as a radical
input (going from 1:1 to 2:1 VSWR) impedance difference, since the output
impedance is set by the amount of High Voltage and plate current.

I find your personal attacks an act of desperation. You seem to be unable
to support your claims technically, since most of your statements
contradict yourself. While you openly contradict yourself, you accuse me
of smoke and mirrors.'

Let me give an example of an obvious contradiction. You claim the Chinese
tube's glass is melted by parasitics, yet you also claim any parasitic
will arc the bandswitch, tuning cap or damage the grid of the tube. In
order to melt the glass, the parasitic would have to have many hundreds of
kilovolts sustained from the anode through the glass to an external
conductor.

You allude to Vectronics using your suppressor, yet you failed to mention after they installed your suppression system field service history did not improve. Your suppression kit was removed from the Vectronics PA's within several months of the initial test.

You cling to the idea that photons cause parasitics, even though a physicist that works in that area disputed your claims. You very clearly said you tested tubes involved in "standby flashovers", and they had no gas. Now you have claimed they DO have gas, like the geiger-muller tube.

The gas filled geiger-muller tube has less than a pico-ampere of current induced by radiation, yet you claim the almost perfect vacuum in a power grid tube tube (that had no gas in the start but now does) will support a large sustance current from external photons.

You claim in most PA's a sudden burst of VHF energy damages grids, bandswitches, and arcs capacitors over, yet we are to believe a Chinese 3-500 has glass failure from the same cause.

I measured the very same style capacitor used in the SB-220, AL-80 series, Vectronics PA's and later Drake PA's, and found no high impedance points up to several hundred MHz, yet you claim these PA's can arc that capacitor over from VHF energy.

You insist a tiny grid rated at 25 watts, will dissipate 500-700 watts. Yet we know the massive 3-500Z anode will become incandescent long before dissipating 500 watts.

None of your claims make technical sense, so you have now reverted to personal slander of me and even NASA. This act of desperation is pitiful.

Gary,

I Strongly agree with the good VOM and scope, but I personally think
the 3rd piece of equipment should be a signal tracer, preferably one
with a tube or FET in the probe for RF tracing. I have used this basic
tool over and over to find difficult to find problems and consider it
the most useful basic troubleshooting tool.

I get laughed at when I drag out my old RCA Senior Volt Ohmist, but I
will not give it up, I'm on my 3rd meter movement.

You should be able to download BAYCOM from the web somewhere. I know
it's small enough to run on a 720K diskette.

I believe there were plans in either Ham Radio or QST several years ago to build 70cm duplexers. I seem to remember they used PC board material.

Maybe someone else will know more precisely when and where the article ran.

Then again, I could be all wrong. They say the memory is the second thing to go...

...snip...
What is the anode resonant frequency in the AL80? You find this with a dipmeter coupled to either side of the dc blocking capacitor. I can not calculate the current distribution without knowing the frequency of the anode resonance. If you do not have access to a dipmeter and an AL80, please let me know and I will call around and see if I can find someone who does.
>
> Your calculations are exact for the values "pulled from your hat", but the

The values of L and R is the actual values we use in the SB-220, TL-922, 2K-4, and similar 2, 3-500Z amplifiers which use a 3000v anode supply.

> A second factor enters the equation, and this is the critical area. Adding
> nichrome to the primary HF path does almost NOTHING to system Q.
...snip...

First things first. I need to calculate the current distribution for 85nH and 100 ohms, but I can not do it until someone uses a dipmeter and measures the anode resonant frequency in the amplifier that this suppressor is used in.

Hi,

I plan to build some DJ9BV long yagis for 144 and 432MHz.

Anyone built some, and have any useful dos and don'ts ?

I plan to use 50R coax rather than the open wire feed, and want to go
for a matching balun like the Eagle Antennas version.

Also, I did see somewhere an address for the insulating rivets in the
UK, anyone know this ??

Thanks

Ed:
Several commercial brands are made from Alum. tubing.
Sinclair makes
one from a square Alum. extrusion. The fabrication is not complicated. The
real trick
is to match the coeffcient of thermal expansion between the center tuning
rod
and the expansion of the outer tube cavity. This is done by using metals
of different expansion rates. The goal is to not have the cavity change
freq.
tuning with temp. The easy way would be to borrow one and copy it. The
metal
which is used in the tuning rod is usually Iconal which is a high nickel
content
stainless steel. Motorola made some out of copper sheet pressed into a
square can
and a couple of small copper straps to tune it. Real cintzy, but they sold
a lot
of them for many years. The bad part is they are almost impossible to tune
properly.
A very poor design.

Set the standing current (no drive) in each tube to be the
same (adjust bias). Apply drive, and adjust the drive level(s)
to each tube to get the same plate current.

If you are really pedantic, now try halving the drive. If there
is a large difference in plate current, replace the lower reading
tube.

I have the flu, and may be a bit hazy today, but let me try to reply.

In article <measures-ya023180002511961001360001@news.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:
> Gain-variation has nothing to do with feedback capacitance.

I never said it did. It is a complex function at VHF in a large tube.

>this will decrease your level puzzlement, Tom: The SB-220 has a VHF
>resonance in the input and a VHF resoance in the output. Both resonances
>happen to be around 110MHz. Approximately 0.2pF of capacitance exists

>reactance. I believe that occasional oscillations at 110MHz can occur in
>the SB-220. The TL-922 has a similar problem at 140MHz, for the same
>reason.

Rich, I think you've looked at the feedback path incompletely or
incorrectly. The input capacitance each tube is 8.3 pF, the feedback
capacitance .07 pF.

With the filament floating perfectly, and the grid grounded, capacitive
feedback is through a 118:1 voltage divider. This of course neglects the
driving impedance of the parallel tubes, perhaps 50 ohms.

The reactance of the feedback path at 100 MHz is through 11,365 ohms Xc,
and the shunt capacitance is 95.5 ohms Xc. Even if the cathode was
resonated by a parallel inductance of 95.5 ohms Xl, the 50 ohm driving
impedance would remain. Voltage division would be through a ~11,000 to 50
ohm divider (with about 90 degrees phase shift).

So if we perfectly resonated the anode and cathode at 100 MHz, we would
have over 46 dB path loss.

Does the gain of a 3-500 tube exceed 46 dB?

What you have failed to see is the oscillation path is not via feedback to
the cathode, it is to the grid. The grid simply looses it's "grounding"
ability due to the shunt capacitance and series inductance of the grid
leads and structure. The cathode is NO part of the oscillation path except
as it couples to the grid. The dominant effect is the anode grid
capacitance, and that's why the grid needs to be compact and the grid
leads need to be very short. We want to move that effect up away from the
operating frequency.

// According to the notes from our telephone conversation in
>1990, you stated that you had worked on over 400 SB-220s, and that many
of

>them had VHF parasitic-oscillation damage. Are you now saying that VLF
is
>what you meant to say?

No, I never said they had VHF damage. I think you have the same tendency we all do, you hear what you like to hear. I only would have said I suspected they had, on occasion, VLF parasitic damage. The grid choke resonates with the parallel capacitors, and the anode blocking capacitor tunes the anode via incorrect loads. With the correct load, we might have a simple TPTG oscillator.

That issue aside, placing any parallel resonant hi Q circuit in the grid leads is idiotic. The grid needs to be grounded with short low impedance leads to the chassis.

That circuit came from what was a good idea, the Collins 30S1 (I think that is the model, the PA with the 4CX1000). In that PA, it provided negative feedback as well as grid current limiting. But it ONLY works in a PA without grid current. Applied to the SB-220, it was a disastrous mistake.

>Tom: What is the grid-resonant frequency in a SB-220 with the
>factory-stock grid circuitry?

I am not positive, it has been over 20 years since I looked at the 220. As I recall it was about 250 kHz with several lower Q resonances below the BCB, and the VHF resonance moved down to less than 90 MHz, depending on lead dress.

>Tom: What is the grid-resonant frequency in a SB-220 with "very very
short
>leads" to ground the grids?

Over 100- 120 MHz.

>Tom: What is the frequency of the anode circuit resonance in an
AL-80...?

That is a complex circuit. There are various frequencies where the reactance crosses zero. Be more specific.

> Tom: You proposed calculating the L/R VHF current-distribution for a
>typical
>3-500Z suppressor. I calculated the VHF current-distribution, and posted
>the results here. Would you prefer to drop this matter?

Current division using simple L/R values is nothing Rich. You used the extreme low reactance range of the suppressor and did it at the low frequency end. Even at that, currents were almost equal. The Q of the non-nichrome suppressor was almost one.

Your claim deals with suppressor Q. My claim was that the resistance dominated the circuit at VHF in a properly designed suppressor, that it was the primary path for VHF currents..while the coil was the primary path

for HF currents. You pushed the example to the edge, still the Q was near ONE with a small conventional suppressor.

Rich, a Q of ~1 is NOT high Q. The conventional suppressor had a Q of 1.14 with a lossless coil. With 5 ohms ESR nichrome it dropped to 1. Is that significant?

Do you really think that very small VHF Q drop has anything to do with less arcing and smoother tuning, or do you think you might be accidentally lowering HF Q?

When you did you suppressor measurements on you Q meter, did you have the resistor in place? If not, your measurements were totally flawed.

I posted the resulting Q change from adding nichrome. Did you find my figures flawed in any way? How much Q change does the nichrome produce? Tell me the wire gauge and I'll do it precisely at two frequencies, at 30 and 100 MHz. Let's see if the nichrome lowers Q more at 100 MHz, or at 30 MHz.

Or would you rather forgo that, and talk about advantages of nichrome. I can think of specific applications where it would be useful for stabilizing a PA.

As per the photons that is silly Rich. Let go of it. Photons are used to explain any energy transfer by electromagnetic disturbances. Your antenna radiates photons, the tank circuit does, so does the tube's filament and anode. Photons are everywhere. You might as well blame the arcing on vibrations. Perhaps a vibration rattles an electron off the cathode and it hits the anode causing a parasitic. That could be why tubes don't last as long in mobile applications, the vibrations shake electrons off and start a parasitic, and the parasitic causes high currents that break the elements of the tube.

When I drop a tube off a shelf, it breaks into oscillation. Tubes should be packed in nichrome packing material, then if they are dropped parasitics won't cause them to fail. That makes just as much sense.

Message-ID: <19961126.004146.4679.0.d.nordquest@juno.com>
Source record: 100370

Rich is surely correct that Challenger shouldn't have been launched. My point, though, was that NASA did not have pictures of 10 previous launches in which fire could be seen -- and was seen -- shooting out the booster rocket's side. That suggests real recklessness. The truth is less melodramatic.

Anyway, Richard Feynman's account can be found in his book "What Do You Care What Other People Think?" A sociologist recently published a book under the title "The Challenger Launch Decision." It handles questions such as Rich raised, but comes to different conclusions.

In another collection of Feynman's writings, "Surely You're Joking, Mr. Feynman," there's a great chapter called "He Fixes Radios By Thinking," which deals with, as I recall, amplifier tubes. I think anyone on this list would love it. Anyway, fixing radios by thinking is what you guys do, while I watch, so have at it.

Dave

I don't remember seeing any exact mathematical calculation for QRO supressors
but I do remember the following rules of complex algebra involved in R/L case.
Let's take R=50 Ohms and L with reactance of 67 Ohms and apply 200 Volts RF.
R current will be 4A and L will carry 3A. Total current will NOT be 7A but
square root of the sum of Ir**2 + Il**2 which equals 5A because of 90 degrees
phase angle. Now we can calculate percentages in AG6K fashion...
But I guess this kind of math in USA might be understand by Oriental students
only while all the others are watching Dow Jones shooting over 7000 mark :-)
I also noticed that Jesse, W6KKT is equal distance from L.A. & Hollywood...

Now Now, Mario

After reading about these "ratios" for days, I too brought this up when I pointed out to Rich that "this ain't DC".

Of course, I was not as succinct as you. I was preferring to, as is said in the literature, leave the solution to the reader <g>.

Source record: 100376

Rich, I think you overlooked this post.

You arbitrarily assigned a value of 50 ohms to the resistor, and .070 uH to the inductor. The AL-80 series uses a 100 ohm resistor, not 50. The inductance of later units was indeed reduced to ~85 nH, mainly due to reduced grid lead and anode lengths, but the earlier models (the "A" series) used about 120 nH. Early AL-80 series units had longer grid and anode paths, requiring larger values of inductive reactance. The SB-220, with its' long grid leads, required more inductance also in combination with less resistance. The typical inductance required in these PA's varied somewhat, but was typically in
the 100-200 nH range.

Your calculations are exact for the values "pulled from your hat", but the actual shift in current varies with the actual supperssor.

A second factor enters the equation, and this is the critical area. Adding nichrome to the primary HF path does almost NOTHING to system Q. I have no idea what guage wire you use, but let's look at some typical suppressors when 5 ohms of ESR is added to the inductor Here are the numbers:

With your suggested values of 70 nH and 50 ohms at 100 MHz.
Q = 1.14 (par equiv values (p eq) are 50r and 70 nH
with 5 ohm esr from nichrome.
Q = 1.0 (p eq) = 44.34r and 70.9 nH

With 70 nH and 100 ohms:
Q = 2.3
with 5 ohm esr nichrome
Q = 1.8 (p eq) = 79.7 r and 70.9 nH

With 150 nH and 50 ohms:
Q = 0.53
with 5 ohms esr nichrome
Q = .5 (p eq) 48.6r and 150.4 nH

(This is the typical 220 suppressor, it has almost a 2:1 current ration in the suppressor, with resistor dominant)

With 150 nH and 100 ohms:
Q = 1.06
with 5 ohms esr nichrome
Q = 1.02 (p eq) 94.7r and 150.4 nH

In all cases, the slightest reduction in load resistance across the coil woul do much more than winding the coil out of a 5 ohms loss material. Of course this considers the non-nichrome coil to be lossless, so the actual

reduction in Q would be less.

From this very small reduction in 100 MHz Q, Rich claims all ills of the PA are cured. No melted glass, no photons, no oscillations, no arcs.

Rich, please explain why you go through the bother of adding a nichrome coil when the Q reduction is so very slight? In almost ALL the cases above, removal of 5-10 ohms of parallel resistance would have changed Q the same amount or more.

> At DC, nichrome alloys are about 57 times more resistive than copper. To
>the best of my knowledge, there is no type of wire that has more VHF
>resistance, and produces a lower VHF-Q on a Boonton Q-Meter, than
>nickle-chromium-iron alloys.

If you measured the coil WITHOUT the loading resistor, as I recall you saying, your measurement method was flawed. Add the loading resistor, and measure the CIRCUIT. You will find almost no measureable change in Q until you lower the Boonton's frequency to HF. If you send me a suppressor, I'll measure it on my HP or Wiltron, they go up over 1 GHz.

I think though we can safely conclude making the coil out of nichrome mainly lowers HF Q, NOT VHF Q.

If any of my numbers are wrong, let me know.

I think Rich is tryng to say organizations lie and try to cover things up.

But organizations don't lie, only the people in them do. This applies to individuals acting alone more than organizations, however. Organizations have checks and balances that prevent this from going on forever.

An organization that doesn't understand their business goes out of business, partially because they waste time and money correcting non-problems. When they finally realize the truth, it is often too late. So it is a self-eliminating problem. Companies that don't know what they are doing, or lie to customers or themselves, die. Companies that are technically strong and honest survive.

Some people lie to themselves, especially when they have a public offering that brings them fame and notoriety. This is pretty common in electronics, a wild theory with no technical merit gets published due to lack of technical review, and it becomes accepted as fact. Eventually, the theory goes so far astray that it falls apart.

Despite mounds of evidence to the contrary, a few people remain believers. Almost like a techno-religion. Most of this occurs in antennas, where circuit theory is difficult to apply and the effect of accelerating charges rippling through the universe at light speed is almost "magical". The only other area of our hobby where it obviously occurs is power amplifiers.

The trend I notice is techno-folklore exists only when the general population is interested in something that is poorly explained. They want to learn, and look for simple answers. The fellow that can give one single answer that applies to any situation is often followed, because even if he is dead wrong.... he is easy to understand.

I see this in my other hobby, automobiles. These wild amplifier and antenna theories are the equal of automotive folklore, such as putting a wooden clothespin or a potatoe on a fuel line to prevent vapor lock.

Myself, I prefer facts when dealing with machines. I save my spiritual side for personal thoughts, and not mystical techo-religious cures. I think I've read enough of this self-contradicting parasite voodoo and the

supporting fabrications (passed off as fact) to last a lifetime.

...snip...
>
> Rich, I think you've looked at the feedback path incompletely or
> incorrectly. The input capacitance each tube is 8.3 pF, the feedback
> capacitance .07 pF.

I have seen spec sheets for 0.07pF to 0.1pF. Are you saying that 2 times 0.07pF is 0.07pF? However, it's a moot point because although feedback C is applicable at HF., at VHF, it's a different ballgame. At 110MHz, add 300nH of lead-inductance to the cathode and the 8.3pF vanishes---and in the SB-220, the cathode dips at 110MHz. Oops.

Your explanation of the VHF un-oscillation mechanism in the 3-500Z is too hazy for me to understand. /// Did anyone understand it?

> // According to the notes from our telephone conversation in
> >1990, you stated that you had worked on over 400 SB-220s, and that many
> of
> >them had VHF parasitic-oscillation damage. Are you now saying that VLF
> is
> >what you meant to say?
>
> No, I never said they had VHF damage.

That raises an interesting possibility, Tom. ....After the caller who identified himself as Tom Rauch agreed with me that Heath SB-220s have parasitic oscillation problems which damages components, I told the caller that I had some bad news. I said: Tom Rauch uses virtually the same suppressor-design that Heath uses in the SB-220. At this point, the caller appeared to "loose it"---rather convincingly I might add. The caller began speaking so loudly that I had to remove the receiver from my ear. I laid the receiver down on the table. A third party, who was across the room could hear the caller's voice plainly.
But of course----if the person who telephoned me was an imposter, then it is absolutely, positively, 100% true that the real Tom Rauch did NOT say

that SB-220s suffer from damage due to parasitic oscillations. Since I mentioned the telephone caller loosing-it incident in my rebuttal, now I think I understand why you wrote the letter threatening me and QST with a libel lawsuit if my rebuttal was ever published in QST. ..... OTOH, the caller was curiously insistent that I NOT tape record the conversation.

>
Nah, it's a simple check with a dipmeter, Tom. I'm beginning to get the impression that someone is trying to complicate simple things in order to lay a smokescreen.

Tom: Does the AL-1500 amplifier, which you designed, use a VHF parasitic-oscillation suppressor?

3304. Looking for 60KHz WWVB receiver circuits

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-26 00:00:00 UTC
From: ctimmons@asic.sc.ti.com
Message-ID: <57f419$h0k@spock.asic.sc.ti.com>
Source record: 100379

Howdy from Dallas Texas,

I'm an electronic hobbist working on an ultimate alarm
clock project. I'm looking for any designs for 60KHz
WWVB recievers. My clock currently uses a battery
backed clock chip for timekeeping but I would like
to upgrate it to use the WWVB signal instead.
I have built a WWV receiver but I find that the
signal fades to much from day to night.

I have seen the article a few years ago in 73 magazine.
Has anyone built this circuit?

Any ideas would be appreciated.

Later-

Yeah, well when the ground shakes a little in Southern California, by the time the story hits the East Coast media, the 'quake is awesome. NBC might have included three incidents of insignificant incidents of o-ring lakage along with the seven serious ones. In any event, NASA lied about whether or not the astronauts survived the Challenger explosion. NASA prevaricated about the reason why they fired the two safety engineers. The lone-holdout from Morton Thiokol, who refused to sign-off on the launch---who was overruled by his supervisor---told this story: About 5 minutes before launch, he was walking down a hallway when he spotted his supervisor sitting in a room watching the countdown on a TV. The supervisor spotted the lone-holdout and invited him to stay and watch the launch. The supervisor informed the lone-holdout that he had just prayed for 20 minutes to almighty God that the launch would be successful, so not to worry. The lone-holdout sat down beside his supervisor and they watched the launch.

>insurance or guarantee.
>73 de Mario, S56A, N1YU.

I agree that Occam's Razor is usually the best course. Certainly a lot
of reported arcing problems are the result of inadvertent light loading.
But I'm not convinced we can blame all arcs on that. I think we can count
on a gassy tube arcing too, and I wouldn't be surprised if VHF oscillations
might not cause problems in some cases as well. (If there were no chance
of that, no amplifier would have VHF suppressors.) So I think that some
protection is warranted if it can save some expensive parts in the event
of a fault, whatever the cause.

I do think that many of Rich's proposed mechanisms are highly implausible.
OTOH, Tom's rather cavalier explanations don't wash either. Amplifiers *can*
break into oscillation. As Chris Bowick says, "The easiest way to make an
oscillator is to try to build an amplifier." Many oscillators *are* hard
to start, and may only oscillate sporadically. Unless you test under
exactly the right conditions, you may not realize you have an oscillator
until someone experiences the condition in the field. (Most FEBs are
issued when a customer finds a problem in the field and engineering has
to come up with a fix.)

I have come to the conclusion that Rich's nichrome inductors don't
do anything useful at VHF. The shunt R lowers the Q nicely at VHF
without adding any series resistance to the inductor. All that does
is introduce extra loss at HF. In some cases that might be useful
if the parasitic is *also* at HF (unlikely with a GG amp, but more
plausible with a common cathode circuit, though ordinary neutralization
or unilateralization are better ways to deal with that), but otherwise
it just lowers amplifier tank Q to no good result.

If tank Q is too high, that's a design or operational problem, and
needs to be addressed directly rather than being bandaided. I am a
very strong believer in addressing real problems and deplore the idea
of using bandaids to merely mask symptoms of an underlying defect.
OTOH, things fail, and operators make mistakes. Design features
which mitigate the impact of failures or operator errors make sense
if they potentially save more money than they cost. (You wouldn't
leave emergency brakes off a car under the assumption that insurance
will cover the damage when the driver crashes due to lack of backup

when the main brakes fail would you?)

>of those $200 radio frequency counters made by Startek or MFJ?

Buy the Radio Shack counter if you must have a counter. It is surprisingly good considering the source (better than MFJ). It's a lot handier than the kits, has more resolution, and covers a wider frequency range too. One big plus of the RS counter over the Startek is that the RS counter is relatively deaf. That means you can use it without it trying to read every radio station in the county. You really have to couple it to what you want to measure (and that's good because it means you won't be measuring something else and not know it).

IMHO, a counter is a lot less useful than it may at first appear. Counters only give reliable readings when fed pure sinewaves. They will often lock to a harmonic or subharmonic of a typical complex signal. *AND YOU WON'T KNOW THAT.* I'd much rather have a scope, even a relatively cheap import scope, than to have a counter. Of course having both is better.

There are two instruments I consider priority purchases for the electronics experimenter. Those are an *analog* VOM and a scope. Later you can add a DVM, a capacitance checker, a dipmeter, a signal generator, a spectrum analyzer, a communications monitor, a counter, etc. Often the best piece of RF test equipment you can have is a good quality transceiver. It can serve as signal generator and communications monitor, and negates the need for a counter in most cases.

DVMs can be almost as devious as a counter. A good old analog VOM can be much more useful because you can spot trending in the readings. That can often tell you a lot more than the dancing digits of a DVM. It also makes checking electrolytic capacitor leakage and transistor junction leakage easy. IMHO, transistor checkers are mostly frills, a VOM will serve. OTOH, I really like capacitance checkers because they

can read small value capacitors and a VOM can't.

>gold-sputtering being caused by an oscillation condition?

Rich,

I tried to avoid this, because it would leave you no way out. I really don't enjoy this, but I see no alternative. You've pushed too hard on this issue and impugned my credibility with "stories", so you can have what you demanded.

The former *R+D engineering manager*, Buzz Miklos, of the Salt Lake City Varian plant has agreed to speak to one or two people on the telephone about your theories. He said he will also come on line, but since he just took a position as engineering manager with another tube manufacturer in PA, it will be sometime in January before he is able to connect directly to this newsgroup.

But if you want a quick answer, let's find someone to talk to Mr. Miklos. A second person still at Varian Salt Lake, John Button, will confirm Mr. Miklos' employment status with Varian, and the fact that Mr. Miklos was indeed R+D engineering manager for Varian and a long term employee in power grid tube design and research. Mr. Brandon will also conform Mr. Miklos' qualifications. Incidentally, both Mr. Button and Reid disagree with you completely also.

Mr. Miklos feels, and says his Eimac engineering staff felt, your theories have no merit and display a complete misunderstanding of how a power grid tube operates and the mechanisms of tube failures.

He prefers you not receive his phone number, since he understands you have more time to argue than he does. He will, however, call you if you always promise to include his views whenever you mention the person assigned to answer customer letters, Mr. Foote.

You wanted to know who at Varian disagrees with you. You now have what you have asked for...and perhaps more than you wanted.

Mr. Miklos said my interpretation of grid damage was correct, that the 8877 can only dissipate perhaps two times the rated dissipation (50 watts) before grid damage occurs. He further stated a major cause of gold sputtering is poor alignment between the grid and cathode bands in the tube, or grid dissipations above the 35-50 watt range.

He also says, as I did, gold migrates slowly on its' own accord from normal electron bombardment. Excessive grid current speeds this process. Excessive dissipation makes the gold migration fatal to the cathode in a very short time.

Let's pick someone to call Mr. Miklos. He will confirm all of this, and as much more as needed. Or we can drop all this parasitic nonsense and do better things.

Your move.

Maybe the jokes aren't funny. But neither is what lawyers are helping to do to our hobby, our country and our world.

People oftn use humor to release frustration and tension. The cost of doing business with and the results of lawyers causes both. No wonder there are so many lawyer jokes.

Perhaps if lawyers had a canon of ethics which kept them from taking frivolous cases, charging exorbanant rates, raping those who win large judgement sums, and taking or making action that hurt groups like amateur radio they would have a some respect from the general public.

Of course, some lawyer will try and justify or nullify the above. That's what they do.

>--
>Gary Coffman KE4ZV | You make it, | Due to provider problems

This depends on the counter. For cheap "ham" type counters,
this is probably fairly accurate. However, many "universal"
type counters, such as the HP 5334B*, have front ends and triggering
circuits that are practically the same as scopes. I.E., you
can set triggering for positive slope or negative slope, and
set the trigger level as well. There is also adjustable
hysteresis, and the input impedance can be selected to work
with a scope probe (1 Megohm input). BTW, the optimum signal
to feed a universal counter is a square wave, not a sine wave.
This reduces jitter.

Above 100 MHz, most counters go to a prescaler mode, with
50 ohm input only, and no adjustable triggering. However,
there are vast difference in performance between well designed
prescalers and cheap ones. For example, the rather expensive
HP 5386 has a GaAsFET preamplifier and static divider IC.
The less expensive 5334B used Si MMIC preamplifiers and a
dynamic divider IC. The 5386 is more tolerant of "funny"
signals and more tolerant of noise.

: Tnx!
: Tim Johnston, KF4FTP
: E-mail: mailto:tim@naxs.com -or- mailto:70333.406@compuserve.com

Tim,
The gamma match is a name for the physical hardware on an antenna used to couple the energy/power that comes from your radio through the coax (typical) to the antenna. The common example is the Aluminum tube trombone type for beam antennas, but there are others.

The gamma can be considered a few different things at the same time, matching the typical 50 ohm coax to the driven element of the beam which has a different complex impedance (ac resistance), you could call it a tuner and/or matching network.

Single band antennas have the classic trombone type design which are frequency dependent. Typical Multi band antennas use a varity of designs which are less frequency restricted and a slightly diff physical design.

Pick up an antenna book or some of the amateur catalogs, better yet an ARRL Handbook has it all and it can prob be found at the local library.

...snip...

OK. I will deal with Mr. Miklos when he comes on the Internet in January.

What is Mr. 'Buzz' Miklos' given first name? Who was Mr. Miklos' immediate supervisor when Mr. Miklos was allegedly employed as"R+D engineering manager" at Varian-Eimac's Salt Lake City division?

Tom:
> Mr. Miklos said my interpretation of grid damage was correct, ...

Congratulations, Tom. However, if Mr. Miklos won't be on the Internet until January, how would he be reading this debate? .... Oops.. ...

You said that Mr. Miklos "further stated a major cause of gold sputtering is poor alignment between the grid and cathode bands " I was not aware that Varian-Eimac was selling amplifier tubes with poor grid/cathode alignment. This is a surprising revelation, Tom. In earlier times, Eimac-quality was excellent. In fact, all of the gold-sputtered tubes I cut open and inspected for the article "Parasitics Revisited" appeared to have correct alignment between the grid and the cathode.

Tom: You said "I tried to avoid this,... ..."---like hang on to your hats, folks, here it finally comes. (trumpets heard off-stage) However, after the smoke and fanfare drifted away, it was abundantly clear to us that you did NOT reveal the name of the anonymous Mr.XXX.

Tom: What is the anode-resonant frequency in the AL-80? Why do you appear to be avoiding the answer to this question?

Tom Does the AL-1500 8877 amplifier, which you designed, use a VHF parasitic oscillation suppressor? Why do you appear to be avoiding the answer to this question?

Let's see here. Is this a 15-rounder, or an unsanctioned non-title fight?

I would have to deduct a point from Mr. Measures for taunting, and award a point to Mr. Rauch for even-temperedness.

However, on these and one other issue on which I am in need of guidance (whether or not to short unused turns in a T-match rotary inductor), I must plead OJ-Jury-Syndrome: it's like the DNA evidence--too complicated--discount it, effectively throwing it out. All I know for sure is that QRO amplifiers look great on their web page, and I need an amp. Although they sure have saved some parts in that HF-2500 with no tuned input circuits.

While Nero fiddles, Svetlana may be getting their act together, which could be good news for all of us (cheaper amps).

Just one idiot's opinion.

Check out the handbooks in the early 80's. For instance the 1981 ARRL Handbook has in addition to the above mentioned 4CX1000, a nice single 4CX250B based amp. 10 watts of drive will result in about 500 watts PEP. You might also check out the July 85 issue of 73. Nice article on a 6M 4-1000 brute. The 23rd edition (and I'm sure others) of Bill Orr's Radio Handbook has a design for a 3-400Z or 3-500Z. This one will produce a KW for 35 watts of drive. I could go on listing other sources but don't think that is necessary. 6M amp designs abound! Not sure where you have been looking but I'd find a different source or find a good Elmer.

Great work Tom!

I follow this thread with anticipation as do many more.

I can't talk 'tubes' like you and Rich do but I do some repair on
amps you all have mentioned.

Rich's grid dissipation rules would sell alot of replacement tubes.
Although I'm sure the warranty would fade away fast.

Enough of that.

Can you tell me why 4 472B PENTA tubes in a Clipperton L lasted
only a few days. I replaced the original tubes and they are still working
but at reduced output which was the reason to buy the new tubes. The
new tubes fell to 100 watts out on 10. Nothing was changed in the
amp..nothing.
Same exciter - FT-767.
Just bad tubes?

the
>SB-220, the cathode dips at 110MHz. Oops.

That's either technical stupidity or the obvious "distortion of facts
game" you like to play Rich.

1.) First, you indicated the P/K feedthrough C was the problem, not me.

2.) I gave the feedback Xc for 0.14 pF (two tubes) , and the shunt
resistance for the driving impedance of two tubes if the cathode was
resonant.

3.) The feedthrough capacitance is internal to the tube, and so the lead
reactance can not cancel the anode-cathode capacitance.

4.) Resonating the cathode would have little or no effect on stability in
a GG PA, the gain is too low and the feedback of the wrong phase.

5.) I actually intentionally resonate the cathode at the third harmonic of
ten and fifteen meters in some PA's to increase efficiency without hurting
IMD or stability.

As usual, your wild guess falls apart upon examination.

>Your explanation of the VHF un-oscillation mechanism in the 3-500Z is too
>hazy for me to understand. /// Did anyone understand it?

Let me clarify it for you. The cathode to anode capacitance is almost always an insignificant part of any stability problem. It is primarily a grid anode problem, but it is a complex problem.

The only case I recall where it is becomes a problem is in the Amp Supply LA-1000 where the control grid is tied to the cathode directly. In that PA, it will oscillate on ten and 15 meters if the loading control is closed and the tuning control rotated. But then, the control grid is tied to the cathode directly. This is still not a VHF oscillation, but rather an HF oscillation.

>> // According to the notes from our telephone conversation in

many
>> of
>> >them had VHF parasitic-oscillation damage. Are you now saying that
VLF
>> is
>> >what you meant to say?

Are these "notes" as accurate and straight forward as your "notes" from the Foote conversation? Did you save "notes" from the Eimac conversations where, in long telephone conversations, the staff explained why you were incorrect?

>> No, I never said they had VHF damage.
>
>That raises an interesting possibility, Tom. ....After the caller
who
>identified himself as Tom Rauch agreed with me that Heath SB-220s have
>parasitic oscillation problems which damages components, I told the
caller
>that I had some bad news.<snip>

Rich, you seem to be losing control. Wild accusations and personal attacks on my character have no place in technical discussions. Your theories either stand on their own merit, or they don't.

The only thing you were ever told, was if you personally slander or tell malicious lies about anyone it might be cause for legal action. That was because of your history of inventing or distorting stories to impugn other persons character.

Life is quite simple Rich. If you confine yourself, like an intellegent gentleman, to the facts and issues, you don't have to be threatened. Say anything you want technically, and anything you say will be fine.

The very reason the person at CPI requested I not allow his name into this conversation is he felt you have a history of public exaggeration, personal attack and slander. That is also the very reason people at Eimac are hesitant to speak to you, they are concerned about being slandered or

personally attacked for merely disagreeing with you. They are afraid that what they say in private conversation will be distorted to suit your personal needs and aired publicly.

You, after failing to respond with good technical answers to questions, have now taken the approach of "if I can't get Tom technically I'll get him personally".

You may have no idea how that behavior makes you look. Most people are intellegent enough to realize technical discussions are technical, and not personal. If I came at you like that, no matter how correct I was technically, most people would be disgusted and write me off as a complete ass.

One offer remains, the former R+D engineering manager has agree to talk to one or two people and explain that your theories are incorrect. He refuses to allow you his phone number (because of the behavior outlined above), but will call you.

If you wish to end this at this point, I understand. I have to say I hoped you would remain a gentleman, I am very disapponted in your behavior. This is not 40 meters. Calm down and think before you reply, please don't be so emotional in public. If you want to cuss me out or call me names, you can do it over the telephone again. But you'll have to pay for the call ! :-)

If you wish to have a technical discussion, get back to the issues and out of the personal attack mode. Do you still want Mr. Miklos and others input? It can now be arranged. You have what you asked for, Varian's engineering and tube designer's final word.

73 Tom

>
>I do think that many of Rich's proposed mechanisms are highly implausible.
>OTOH, Tom's rather cavalier explanations don't wash either. Amplifiers *can*
>break into oscillation.

I never said amplifiers "can't" oscillate. I just indicated that by proper design and testing the likelyhood of oscillation can be reduced to zero. My point was a properly operating PA does not go happily along for weeks, months or years and suddenly require a transfusion of nichrome.

My point is a linear PA with near critical feedback doesn't suddenly break into oscillation and produce currents that destroy components like tubes. The very mechanics of oscillation prevent that, let alone emission limits in the tube.

By far the most destructive oscillations are those that occur near the operating frequency. Dentron Clippertons do this, because the 4 572B tubes are unstable in the upper HF regon.

In over 20 years of commercial PA design and 34 years of amateur PA design and construction I have never found a PA that "oscillates" in the field through a defect or fault rooted in the PA that can not be made to oscillate in a test situation.

That's not a guess, it's a fact.

Re Amplifier using 304tl tube.....
Many transmitting tubes become defective with age, even if stored carefully, due to gas intrusion through the metal to glass seals over time. The 304 TL tube is a very old design....you might want to verify it's usable condition before you design an amp around it. Also, to design an amp is a very satisfying project. I wish you luck, and also, I found that friendly talks with FM broadcast engineers, particularly with those who mainain 1 or 2 kw FM stations to be valuable. Many use 4-400A based transmitters, and sometimes have spare tubes available to radio amateur builders....I built my first KW amp around 4-400A tubes that I got at no cost from the local broadcast engineers...
good luck....

> point to Mr. Rauch for even-temperedness.

Mr. Rauch has repeatedly not answered simple questions like whether or not he incorporated a VHF parasitic- oscillation suppressor in the design of his AL-1500 amplifier. The answer is either yes or no.

Mr. Rauch proposed that I calculate the VHF current distribution in the AL-80's parasitic suppressor. Three things are needed to do the calculations. L, R and the frequency (of the anode resonance). Mr. Rauch states that L is 85nH, that R is 100 ohms, but despite an abundance of requests from me, he has so far not stated what the frequency is.

ï¿½ Roger: how many points would you award to each pugilist for evasiveness?
>
> However, on these and one other issue on which I am in need of guidance
> (whether or not to short unused turns in a T-match rotary inductor), I must
> plead OJ-Jury-Syndrome: it's like the DNA evidence--too complicated.

If you enjoy seeing eyebrow-raising, eye-popping, coil-to-frame arcing at the open end of the inductor, DO NOT short the unused turns. OTOH, if you would rather loose a few watts, and forgo the arcing, short the unused turns.

However, I absolutely, positively, 100% have no idea whatsoever how one can gash one's finger on a cellphone.

Alas, this debate was not my idea, Roger. Since 1990, Mr. Rauch has indicated that he wanted a public debate with yours truly about the subject of parasitics. Debating with Mr. Rauch has so far been like trying to play poker with a guy who proudly declares he has the winning hand, but refuses to lay his cards on the table.

Hi Mario-

Well, unless I missed something, the total current through the
suppressor was not the point of disagreement. It was how the current
was divided between the inductor and the resistor.

In your example above, how does the phase shift alter the balance of
current between the two legs of the circuit?

Thanks and 73,

Tom KJ5IE

Hi Carl,

Would you (or any other person) like to talk to Mr. Miklos about tubes, and report back to us about his opinions of Measures articles and suggestions? He hasn't the time to get on now, but he would be willing to answer questions on the land line.

If you had time, a few other Eimac and ITT design engineers might also be located. You could tell us in your own words what their opinions of Rich's theories are.

In article <19961127154600.KAA28742@ladder01.news.aol.com>, the2x4@aol.com writes:

I don't know Carl. Anything I say would be a guess, unless I had much more information. I am working with some 572B's now in a homebrew PA, but the circuit I have used is quite different than the Dentron.

I don't think highly of the Dentron design. It has a very poor layout, and the tubes are not neutralized. I am also not sure of the reliabilty or service history of Penta 572B's.

I'd like to have any information I could about them. Did the tubes work correctly initially? Can you describe in detail how the failed? Do the old tubes still work the same? Who was the vendor, what was the country of origin?

suppressor
>is used in.

Resonance tells us nothing about impedance, except the reactance cancels
or crosses zero. Even though you do not understand VAR power, phase shift,
or Q I still expect you should understand a very simple concept like
resonance!

A circuit at resonance could look like zero ohms, infinite impedance, or
anything in between. So even if we know the frequency of resonance, we
know nothing about the impedance of the circuit and can do no
calculations.

Why ask for meaningless data? What is it you want to do, and I will tell
you what numbers you need to do that.

Tom

3350. Re: Band pass filter for 144MHz reqd?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-27 00:00:00 UTC
From: Steve C <Steve@mjrigby.demon.co.uk>
Message-ID: <OYw$VAAVIKnyEwpM@mjrigby.demon.co.uk>
Source record: 100288

Hi Ian,

>Is this the right question?

Well, I think so..

The prob is thus:

I operate on a portable site near a commercial mast. We get some QRM
which shuts down the rig almost completely. I think this is caused by
the mast, maybe taxi band, or even police YK type repeaters.

My idea is to band stop all but 2m and see the results.

I dont always use the same rig, so I want a filter to put in line,
preferably after the amp, so that if it works, I can have it before the
amps' pre-amp.(Not got mast-head :-(

>Very cheap and effective harmonic notch filters cut from ordinary coax
>were described by G4SWX in RadCom about a year ago.

Now this is a good point, I had overlooked this.

(Has been to work and tried it...)

I tried a simple quarter wave stub, which gave a great notch, and tried
shorting it.(Was sure read shorted stub opposite of open) but not really
any good.Just a notch at 2 lambda.
Is there a simple coax bandpass I can try ?? (I can sweep from 400hz to
2500Mhz, so can look all over...)
I did notice the notch was only about -40dB (though our power head
doesn't go much lower, it wasn't noisy at all so I trust it) and
sometimes was only -30dB.

>If this is a breakthrough problem, you can probably have your station
>officially inspected and your equipment checked by the Radio
>Investigation Service at no charge - e-mail me for details.
>(Limited offer, applies in Britain only :-)

I've used the open quarter wave (if remember right) as filters for
neighbours, worked very well.(Which is why I should have thought of a
coax filter :-)

Thanks for the reply..

>
>Tnx!
Hi Tim,

A gamma match is a good way to feed an unbalanced feeder (coax) to a
balanced antenna (the dipole on the yagi).
It is essentially a capacitor and an inductor (simply).
The shield of the coax is connected to the centre of the grounded (to
boom) driven element. The inner goes through a capacitor (which can be a
real capacitor, or a rod inside a tube insulated from it) into an
inductor which normally runs parallel with one side of the dipole, and
is shorted to it at some point.

Its actually an easy feed to homebrew...

> Why ask for meaningless data?...snip....

At this point in the debate I need a volunteer who owns an AL-80 or SB-1000, who has access to a dipmeter, to measure the anode resonant frequency. (Be sure to disconnect the electric-mains plug before performing the measurement.) The best place to measure the dip is at the DC blocking capacitor. The resonance is probably between 110MHz and 160MHz. The dip should be sharp and pronounced. Set the tune capacitor to about 50% of C maximum. This measurement is needed in order to be able to solve the current division problem for the 85nH inductor and 100 ohm resistor parasitic suppressor that Mr. Rauch suggested.

Please telephone me collect if you make this measurement.

Tom: Does the AL-1500 8877 amplifier, which you designed, use a VHF parasitic oscillation suppressor?

Content-Type: text/plain; charset=us-ascii
Content-Transfer-Encoding: 7bit
X-Mozilla-Status: 0001
Content-Length: 830

Hi,

A friend of mine (Bill, N4VMY) would like to find a source of the
ceramic plug in coils manufactured by E. F. Johnson prior to WW2. The
ones he wants are wound on ceramic forms, rated at 500 watts and are
mounted on a 5 pin plug bar. He has a complete set of the 150 watt ones
(which he calls the grid coils) and wants the 500 watt ones (plate
coils) to complete an AM transmitter. There is a picture of these in the
10th Radio Handbook on page 650 (in the ad section) but there are no
part #'s listed. If anyone has part #'s for these coils, I would
appreciate those too.

After the war in about 1948, Johnson introduced the air wound coils with
the swinging link deal, so the only pictures in the handbooks of these
ceramic ones should be in the pre 1948 or pre war publications.

Thanks,

Chuck, KE9UW

I don't have a C26 DSK but I do have a couple C50 DSK's, as far as I know the only real difference between the C26 and C50 except minor architectural improvements is that C25/C26 use 4 clocks per instruction while the C50 uses only two so the C50 should always be twice as fast, and should be 100% compatable will all code as long as C25/C26 complatability in specified in the compiler/assembler. E-mail if interested.

>KT4XW
>Keith Spainhour
>KSpainhour@wilkes.net
Remember one thing about the 304 TL, It is like 4 75TL tubes
in parrallel. So it has a much lower plate impeadance than most
other power tubes. It was designed for higher than expected plate

currents. Also the TL designation means it is the low gain version.
The high gain triodes provided about 10-13 db of gain, and the low
gain versions about half of that, or 5-6 db in the original circuits.
304's make great AM modulator tubes but I don't know about their
rf merit. Certainly many hams used them for rf anyway.

:)N3SPD

: It is a noise-reduction scheme. Most of the noise in FM systems is what
: might be termed "high frequency" or "hiss" (similar to tape). So the
: high frequencies are "pre-emphasized" (i.e. get more gain than the lower
: frequencies). Then when played back, the high frequencies are
: "de-emphasized" (get lower gain). This raises the overall signal/noise
: ratio.

: Similar schemes are used in tape decks, and on vinyl records (RIAA
: equalization, also called 75us equalization). Dolby is a similar scheme.

With reccords, the velocity of the needle is lower at low freqs, so the
signal is much lower in amplitude. SO the EQ curve has more gain at lo
freqs. THat's the opposite of FM which has equal gain up to 2 kHz, then
the gain falls off.

Dolby isn't a static equalization, it's dynamic.

Source record: 100300

Hi Rich,

You must be having E-mail trouble. Could you look this over an comment. It seems to indicate you do not understand Q. Could you tell me if I did something wrong?

>>
A second factor enters the equation, and this is the critical area. Adding nichrome to the primary HF path does almost NOTHING to system Q. I have no idea what guage wire you use, but let's look at some typical suppressors when 5 ohms of ESR is added to the inductor Here are the numbers:

With your suggested values of 70 nH and 50 ohms at 100 MHz.
Q = 1.14 (par equiv values (p eq) are 50r and 70 nH
with 5 ohm esr from nichrome.
Q = 1.0 (p eq) = 44.34r and 70.9 nH

With 70 nH and 100 ohms:
Q = 2.3
with 5 ohm esr nichrome
Q = 1.8 (p eq) = 79.7 r and 70.9 nH

With 150 nH and 50 ohms:
Q = 0.53
with 5 ohms esr nichrome
Q = .5 (p eq) 48.6r and 150.4 nH

(This is the typical 220 suppressor, it has almost a 2:1 current ration in the suppressor, with resistor dominant)

With 150 nH and 100 ohms:
Q = 1.06
with 5 ohms esr nichrome
Q = 1.02 (p eq) 94.7r and 150.4 nH

In all cases, the slightest reduction in load resistance across the coil woul do much more than winding the coil out of a 5 ohms loss material. Of course this considers the non-nichrome coil to be lossless, so the actual reduction in Q would be less.

From this very small reduction in 100 MHz Q, Rich claims all ills of the PA are cured. No melted glass, no photons, no oscillations, no arcs.

Rich, please explain why you go through the bother of adding a nichrome coil when the Q reduction is so very slight? In almost ALL the cases above, removal of 5-10 ohms of parallel resistance would have changed Q the same amount or more.

> At DC, nichrome alloys are about 57 times more resistive than copper. To
>the best of my knowledge, there is no type of wire that has more VHF
>resistance, and produces a lower VHF-Q on a Boonton Q-Meter, than
>nickle-chromium-iron alloys.

If you measured the coil WITHOUT the loading resistor, as I recall you saying, your measurement method was flawed. Add the loading resistor, and measure the CIRCUIT. You will find almost no measureable change in Q until you lower the Boonton's frequency to HF. If you send me a suppressor, I'll measure it on my HP or Wiltron, they go up over 1 GHz.

I think though we can safely conclude making the coil out of nichrome mainly lowers HF Q, NOT VHF Q.

If any of my numbers are wrong, let me know.

73 Tom<<<

When you answer this, and we resolve any errors I''ll move on to one of your questions.

By the way, a grid dip meter will not allow you to calculate anything about impedance in a complex system, surely you understand that much about RF?

73 Tom

Nice answer....
It is indeed. The YAGI feedpoint is about 20 ohms.

Yes, I have the time to talk to Mr. Miklos and others.

The 572B's were installed and all appeared OK. I was not
there when they failed. The exciter was a FT-767. I did however
put the old tubes back in and they worked at their previous
output before the Pentas were installed which is about 600 watts.
These old tubes are in fact still in use after two years. Upon initial
installation
the 4 Penta's output was a little low but not enough to be concerned with.
My customer still has the old tubes and if I get a chance I'll check them
out.
Rich asked if pieces of the tube innards were floating around. I don't
think so but I'll look again. If fact the tubes looked brand new just
dead.
I wish I could tell you more.

I had a similar case last week with a SB200. In fact it is still here
waiting to
be picked up. A previous owner other than my customer had installed a
standby switch and messed up the bias placing -130 some odd volts on the
bias line at all times

My customer bought it and couldn't get the amp to put out more than 100
watts, so he bought a pair of new Russian tubes from RF PARTS then brought
it to me.

The old tubes were Certron and ended up doing about 350 on 80. Exciter was
an
FT-757. I installed the new, still in the taped up boxes, Svetlana tubes
and only got 100 watts or so output. Same exciter, same amp. What gives? I
made no attempt to delve further in to the situation. Just thought you
might provide an answer from a similar problem. I think these tubes are
terrible! I would hope they are direct replacements and I'm sure everyone
else assumes that. How can they sell them? Why do the offer them for sale?
So they are cheaper. That won't get you across
town with these tubes.

Nope, Carl. I haven't spotted any rust. I have heard reports of virtually
new Penta 572Bs that wound up with broken filament wires. Did notice that
the light from the filaments went out in the 572Bs that failed? Were the
grids directly-grounded in the amplifier?

Hello, Tom---

Nah, you haven't done anything wrong yet--if you are trying to play this debate for stalemate instead of checkmate. It is true that if you continue to stonewall embarrassing questions, stall, and smokescreen, I will eventually walk.

Either you are reluctant to admit that you don't own a dipmeter with which to make the anode-resonance measurement that we need to proceed, or you don't have access to an AL-80, or you are trying to misdirect attention away from the problem that you proposed---i.e., to find the current ratio in the 85nH (Ls) and100 ohm (Rs) parasitic suppressor which you use in one version of the AL-80. I am starting to lean toward the latter possibility.

Tom: In order to try and get a handle on what's happening, I will give you the benefit of the doubt and guesstimate that the anode resonant frequency in the AL-80 is 160MHz, although I seem to recall hearing a lower number from AL-80 (and SB-1000) owners. Using the formula XL=2*Pi*f*L, at 160MHz, 85nH has 6.28*1.6*10^5*85*10^-9=85.4513, or roughly 90 ohms of reactance. To find the current distribution, we can apply 1V to the paralleled Rs and Ls. The resulting current through Rs is 1v/100 ohms = 10mA. The current through Ls is 1v/90 ohms = 11.1mA. The total current is 10mA plus 11.1mA = 21.1mA. The current through Rs is 10/21.1 = 0.474 of the total current. The current through Ls is 11.1/21.1 = 0.526 of the total current. If 52% of the VHF current is flowing through Ls, and 48% of the VHF current is flowing through Rs, there is obviously a large hole in the opinion Tom Rauch has held since 1990--i.e., that no significant VHF current flows through a VHF parasitic-suppressor's L. The bottom-line is that in the typical VHF parasitic-oscillation suppressor, significant current flows in Rs and significant current flows in Ls.
However, in actual practice, the anode-resonance in the typical single 3-500Z amplifier is closer to 130MHz,, so the reactance of Ls would be lower and Ls would carry a slightly greater share of the current---and the hole in Tom Rauch's opinion seems to grow larger.. OTOH, it can be argued that the intrinsic VHF-R in nichrome would slightly decrease the current in Ls. ....All things considered, significant current flows in Rs and

significant flows in Ls.

On page 74 in the September, 1994 issue of QST, Tom Rauch states:

"The coil's reactance increases with frequency and at VHF most of the
signal path is through the resistor. It is plainly evident that the
dominant component at VHF is the resistor, not the coil."
(note: Mr. Rauch appears to use the word "coil" in place of the word inductor)

It is PLAINLY EVIDENT that neither Tom Rauch nor QST Editor Mark Wilson
took the humble minute necessary to perform the calculations to check the
validity of Tom's statement before it became a sorrowful chapter in QST
history.
This easily-preventable blunder would NOT have happened in the days when
George Grammer, W1DF, stood watch over the technical reputation of QST
magazine. According to those who knew him, George Grammer placed nothing
above technical accuracy.

3375. TL922 Arcing/Oscillating? Help with diagnosis?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-28 00:00:00 UTC
From: "David B. Holtkamp" <holtkamp@roadrunner.com>
Message-ID: <01bbdd57$e8537f20$8f6d3bc6@holtkamp.roadrunner.com>
Source record: 100313

I have a several year old TL922A (mod for 10 m) and I've been having some trouble with it arcing (or oscillating - can't tell which). The details are in the next paragraphs, and I'd appreciate any help/suggestions on what to try next.

When I got the TL922 (from a silent key's estate), I noticed that the plate capacitor exhibited arcing damage - the position corresponded to a lower capacitance setting (little capacitor area active). The arcing had pitted and melted part of one of the plates (the fixed position one). I cleaned it up as best as I could (filed off, smoothed and straightened the plates, etc.) I used it for several more months and then it began arcing more or less steadily whenever I tried to tune up. I usually operate SSB with the HV setting on the lower (CW) setting in the amp. I don't push the amp particularly hard - usually running about 500 w out. Our altitude here is about 7000 feet so HV may have a little more trouble with arcing than at sea level, but I'm not sure that this is a contributing factor.

I replaced the tuning cap with a new one from Kenwood (~$120!!) and hoped that my problem was solved . I figured that the arcing was due to surface roughness and pitting that I really couldn't fix and I hoped that the new one would solve my problem.

Well, as you may have gathered by now, it has started arcing again. I'm very careful to tune it into a nice low SWR load (G5RV + tuner or a 5 el log periodic), but I have problems with arcing at full output (~600 w) on 160m and somethimes the higher bands (15 and 20 in particular).

I also found earlier that trying to use SSB on the SSB HV position would almost invariably cause arcing so I don't even try to use the higher voltage settings. I can always tune it up successfully at low power 200 w or so, but then why bother with an amp?

I've seen AG6K's material on his web pages (Thank you!), but I'm not sure that VHF parasitics are the cause of my problems (although they may very well be!). I've looked elsewhere on the web with little luck (so any pointers to other sources would be appreciated).

So the following questions come to mind:
1) am I "arcing" or suffering from VHF parasitics? How can I tell the difference?
2) I haven't suffered (I think) any damage to tubes or resistors or other components in the TL922 (yet) - should I be on the lookout for other damage? What should I look for?
3) Can this problem be aggravated by RF in the shack? I have a modest amount of it I'm sure...
4) Should I pass on the TL922 and buy a more modern design? If so, what is

the recommendation?

Thanks in advance for all your help!!!

Best regards,

David Holtkamp (K5KH)

Tom: In order to try and get a handle on what's happening, I will give you the benefit of the doubt and guesstimate that the anode resonant frequency in the AL-80 is 160MHz, although I seem to recall hearing a lower number from AL-80 (and SB-1000) owners. Using the formula XL=2*Pi*f*L, at 160MHz, 85nH has 6.28*1.6*10^5*85*10^-9=85.4513, or roughly 90 ohms of reactance. To find the current distribution, we can apply 1V to the paralleled Rs and Ls. The resulting current through Rs is 1v/100 ohms = 10mA. The current through Ls is 1v/90 ohms = 11.1mA. The total current is 10mA plus 11.1mA = 21.1mA. The current through Rs is 10/21.1 = 0.474 of the total current. The current through Ls is 11.1/21.1 = 0.526 of the total current. If 52% of the VHF current is flowing through Ls, and 48% of the VHF current is flowing through Rs, there is obviously a large hole in the opinion Tom Rauch has held since 1990--i.e., that no significant VHF current flows through a VHF parasitic-suppressor's L. The bottom-line is that in the typical VHF parasitic-oscillation suppressor, significant current flows in Rs and significant current flows in Ls.
However, in actual practice, the anode-resonance in the typical single 3-500Z amplifier is closer to 130MHz,, so the reactance of Ls would be lower and Ls would carry a slightly greater share of the current---and the hole in Tom Rauch's opinion seems to grow larger.. OTOH, it can be argued that the intrinsic VHF-R in nichrome would slightly decrease the current in Ls. ....All things considered, significant current flows in Rs and

significant current flows in Ls.

On page 74 in the September, 1994 issue of QST, Tom Rauch states:

"The coil's reactance increases with frequency and at VHF most of the
signal path is through the resistor. It is plainly evident that the
dominant component at VHF is the resistor, not the coil."
(note: Mr. Rauch appears to use the word "coil" in place of the word inductor)

It is PLAINLY EVIDENT that neither Tom Rauch nor QST Editor Mark Wilson
took the humble minute necessary to perform the calculations to check the
validity of Tom's statement before it became a sorrowful chapter in QST
history.
This easily-preventable blunder would NOT have happened in the days when
George Grammer, W1DF, stood watch over the technical reputation of QST
magazine. According to those who knew him, George Grammer placed nothing
above technical accuracy.

>was made from resistance wire instead of copper wire.

That does not appear to be what Mr. Handy was saying at all. The quote indicates that a combination of an inductor and a resistor is very effective as a parasitic suppressor. That advice is, of course, correct, and is the way *every* parasitic suppressor is made today. Even yours. The resistance needs to be in *parallel* with the reactance, however, not in series with it, for best results.

>Nichrome has the
>highest volume-resistivity among resistance wire alloys, but it is not

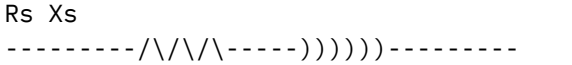
>large amplifier tubes did not exhibit very much VHF gain. With modern,
>high-gain amplifier tubes, VHF suppressors with a high VHF-dampening
>ability seem to be indicated. High VHF-dampening means low VHF Q.

Indeed, which is why there is a *paralleled* resistor across the inductor, to lower the suppressor's *VHF Q*, or more to the point, to increase the suppressor's *dissipation* at VHF. At *HF*, however, we want high Q so that we don't have attenuation of the *desired* HF energy. That's why the coil is made of copper (silver plating *is* mostly cosmetic). The reactance

of the coil is *non-dissipative*, but any series resistance in the coil *is* dissipative. That's bad because we want HF energy to have free passage through the reactive branch of the suppressor.

Lets look at a couple of circuits. This one is equivalent to your nichrome coil.



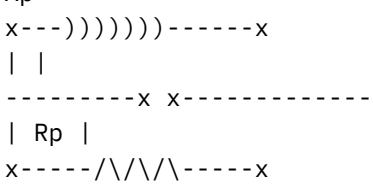
Q is just Rs/Xs, and for a given current I, the power dissipated in the circuit is simply

P = Rs*I^2 + PF*Xs*I^2

Now the PF of a pure reactance is zero, so the attenuation of the circuit is simply Rs*I^2.

Of course the value of I is dependent on the total impedance of the branch, IE Z = R +jX, and X is dependent on frequency. The higher the frequency, the greater the value of X, the lower the I through the circuit, and the lower the power dissipated in Rs. So the circuit dissipates maximum power at lower frequencies and dissipates least at higher frequencies, exactly opposite of what we want a VHF suppressor to do.

Now lets change things around.



Now we can use a transform to get the equivalent series resistance and reactance of this circuit like so

Rs = (Rp*Xp^2)/(Rp^2 + Xp^2)

Xs = (Rp^2*Xp)/(Rp^2 + Xp^2)

The equivalent Q is

Qe = Rs/Xs = (1/Rp) * Xp/(Rp^2 + Xp^2)^2

As Xp increases, Q falls rapidly due to the Xp^4 term in the denominator.

For a current, I, flowing through the circuit, I divides between the Xp branch and the Rp branch in inverse proportion to their impedances, and only in the Rp branch is any power dissipated. When Xp is high (VHF) more current flows in Rp, and dissipation is high. When Xp is low (HF), less current flows in Rp, and dissipation is low. PF=0 in the Xp branch of course, so no dissipation occurs there. This is exactly what we want a VHF suppessor to do. If we were to add series resistance to the coil,

as you do, then our dissipation at low frequencies would also be high, which we don't want since it adds nothing to stability but does decrease HF efficiency.

Gary

Hi all,
I hope this is the news group to use. ?

This is a program I put together to do the math for me.
use QBASIC or GWBASIC to check it out.

How do I make it so all you have to do is pick the dB ATT.
value and the watts to give me the answer.

Any help would be GREAT !

Dave,n1iqo

In almost all of the launches, a puff of smoke can be seen coming
from the SRB joints at engine start. This is normal behavior for
this sort of joint design. Internal pressure tightens the seals,
but until that pressure builds up, some gas leakage is expected.
This is different from O-ring erosion or O-ring failure. Some people
have claimed that this smoke indicates flame leakage, but it doesn't.
The flamefront of the engine is not yet at the level of the joint
when the smoke is seen.

>Perhaps Rich is preparing us for the revelation that the O ring failure
>was due to a parasitic oscillation, or perhaps photons from a solar flare
>caused the failure.

Actually, parasitic oscillations (mechanical resonances) were one of the
potential causes examined during the Challenger investigation. It isn't a
silly idea, and it turns out the joints do suffer hoop flex during operation.
Thanks mainly to Feynman, we know the proximate cause in the Challenger
disaster was O-ring brittleness caused by the cold temperature at launch.
That doesn't mean that was the only failure mechanism to which the SRBs are
subject. The bandaids fitted by NASA and Thiokol after Challenger were mainly
to address this resonance issue (the O-ring problem was addressed by changing
the launch rules to prevent launch when the field joints were too cold).

>Other than that, I'm having a hard time understanding what this has to do
>with all his wild theories and claims about parasitics.

I expect he is trying to say that large organizations (or small ones
either) don't always owm up to their design failures. Rather, they try

to hide them or discount them or bandaid them, even when a catastropic public failure brings them to light. NASA knew there was a problem with the SRB field joints, but chose to ignore it. Thiokol management knew there was a problem with the SRB field joints, but chose to ignore it. When the two on-site Thiokol engineers advised against launch, NASA management and Thiokol management ridiculed and browbeat them, and proceeded with the launch anyway. The result was spectacularly obvious, and tragic.

After Challenger, not only was the weakness of the O-rings to cold exposed, but other problems with the joint design were brought to light as well. NASA and Thiokol put some bandaids on, but the joints are still a serious failure hazard to this day. There have been recent launch delays due to concerns about the joints.

There is a proper technical solution to the problem, which completely eliminates the field joint issue, but it was not designed by NASA or Thiokol, so it has not been put into service. That bit of "not invented here" (driven by some very heavy politics) may yet come back to bite NASA. Rich may be implying that there is a large dose of "not invented here" behind the opposition to his suppressors too.

Sidebar;

The politics mentioned above involves producing the SRBs in Utah, which necessitates segmenting the boosters to allow their transport by rail to the Cape. This was done to "buy the vote" of the Utah delegation in Congress. The competing solution was to have the boosters built in Mississippi by a Thiokol competitor. They would have been barged from there to the Cape via the intercoastal waterway non-segmented. That eliminates the joints, and any possibility of joint failure, entirely. Cost and weight would have been lower too.

Politics is generically why space hardware is made all over the place instead of being constructed near the launch site. At least for large components, construction near the launch site would be the rational thing to do, but only buys the vote of one state's Congressional delegation. Space pork had already been spread throughout the South where barge shipping to the Cape was practical, so the boosters wound up being made in Utah to buy that distant landlocked state's vote too. Pork barrel politics is a nasty business, and it cost 7 lives. But without it, there likely would be no manned space program, because short sighted legislators can't see past their next re-election campaign, and "bringing home the bacon" is a proven re-election strategy.

KeyCAD Complete 29.95 from Softkey 407-367-1415 is a complete
cad program. The CDROM version has a large number of libraries
electric/plumbing/etc. You can also add to the library yourself
or buy same from them. It will do layers if you need them, as it
is a full cad drafting program it can scale, replicate , etc.

Comes in both DOS and MAC flavors.

> Yes, I have the time to talk to Mr. Miklos and others.

Mr. Miklos needs to speak for Mr. Miklos. Mr. Rauch proffers the story that Mr. Miklos can't get on the Internet until January. I am on ISP number three. It takes me about an hour to get set up with a new ISP---and I am no computer genius by any means. Apparently, Mr. Rauch does not even know Miklos' first name or the name of Miklos' ex-supervisor at Varian-Eimac's Salt Lake City div. Hmmm. I suspect that the story about Miklos is a Rauchian ruse to play for time---like the "Tom: does the AL-1500 amplifier use a VHF suppressor?" issue. Tom knows that if he answers yes, then I am going to point out that he said a parasitic suppressor was not needed in an 8877 amplifier. Mr. Rauch knows full well that eventually I will tire of stalling, bs, and hogwash---whereupon I will bail out---whereupon Mr.Rauch will proudly proclaim a draw. // BTW, Carl, would you like to take a wild guess whether or not Rauch's AL-1500 amplifier uses a VHF suppressor?

> I wish I could tell you more.

Did the customer report hearing a noise at the time the tubes died? If you do not recall whether you noticed the filaments lit up in the dead tubes, Carl, then we will have to wait for the second encounter.

I have heard that the newer 572Bs have a somewhat higher mu than the Cetron and RCAs. One indication of higher mu is if you see a change in input SWR when the new tubes are in use. The higher the mu, the less cathode to filament RF voltage is needed to drive the tubes to the same cathode current. Thus, the driving Z decreases with higher mu tubes, and that affects input SWR. With a solid-state driver, higher input SWR means less RF out, so output from the amplifier should decrease accordingly. Higher mu also means higher gain, which means more ability to oscillate. RF Parts is reportedly aware that the failure of Penta 572Bs in SB-200s is parasitic-related. Cetron tubes are not a sure cure, either. I have heard of a number of SB-200 owners who had the bandswitch's Wafer A contacts for the 100pF tune-cap. padder, burn up from parasitic arcing when brand new Cetrons were installed. The next time you work on a SB-200 with sudden

tube failure or a burned bandswitch, take a dipmeter and check the VHF dip
at the 1000pF, 5kV DC blocking capacitor. Is the dip sharp or broad?

I have network analyzers and other RF impedance measurement devices. And
yes, I even have a grid dip meter.

The point remains what can you possibly do with a grid dip meter Rich? It
won't tell you a thing about the impedance of the system, other than
reactance crosses zero at some frequency near the dip. Big deal.

Why waste time with a useless exercise. You came to circuit analysis
class, put away your drycell and buzzer and get out an instrument.

> Tom: In order to try and get a handle on what's happening, I will give
>you the benefit of the doubt and guesstimate that the anode resonant
>frequency in the AL-80 is 160MHz

You have an uncanny physic ability Rich. You can guess things that
instruments can not measure. I'm sure, when you know the resonant
frequency, you will "guess" the real part of the impedance. And the
imaginary pats distributed in the system as well.

Will this new "guess" be better than your guess about the photons that
cause tube arcs in a tube that has no gas. Or like that guess, and one
that conveniently allows you to change it to a tube WITH some gas.

Is this like your "guess" that Eimac rates the grid of an 8877 at 25
watts, but it is really 500-700 watts?

of
>the VHF current is flowing through Rs, there is obviously a large hole in
>the opinion Tom Rauch has held since 1990--i.e., that no significant VHF
>current flows through a VHF parasitic-suppressor's L.

You do not even understand the concept of current flow in a circuit with reactance. All you have shown is the Q is just over one.

You made a mistake in the total current. The coil is an energy storing and releasing reactance, not a resistance. The amount of energy storage is given by the Q. Perhaps the lack of understanding of circuit behavior is at the root of your bad science???

The Q is just barely over one. How much lower can nichrome make the Q go? What is the lowest practical or possible Q?

You have claimed, before the whole world, that your suppressors lower VHF and UHF Q. You claim all sorts of system benefits due to VHF and UHF system changes, yet you just demonstrated the Q is near unity in the conventional suppressor. If the Q is near one, we know adding nichrome can't lower it any significant amount. If nichrome can't lower the Q, then all your claims are wrong.

The Q is already so low if we remove the coil entirely and make the suppressor a pure non-inductive and capacitive resistor we can only reach a Q of zero!!

If we include the rest of the system, we would find even less change than that, because the Q could not even reach zero.

> It is PLAINLY EVIDENT that neither Tom Rauch nor QST Editor Mark Wilson
>took the humble minute necessary to perform the calculations to check the

Hi Dave,

In article <01bbdd57$e8537f20$8f6d3bc6@holtkamp.roadrunner.com>, "David B. Holtkamp" <holtkamp@roadrunner.com> writes:

>When I got the TL922 (from a silent key's estate), I noticed that the plate
>capacitor exhibited arcing damage - the position corresponded to a lower
>capacitance setting (little capacitor area active). The arcing had pitted
>and melted part of one of the plates (the fixed position one). I cleaned it
>up as best as I could (filed off, smoothed and straightened the plates,
>etc.)

You can not fully restore a capacitor's voltage breakdown by this method. The voltage gradient at any point is determined by the radius of the plate, and any microscopic burrs and points.

To give you an example, the plates of a capacitor are tumbled in something as mild an abrasive as walnut shells for several hours to polish them. Even the slightest nick or scratch on the surface will lower the voltage breakdown.

>I used it for several more months and then it began arcing more or
>less steadily whenever I tried to tune up. I usually operate SSB with the
>HV setting on the lower (CW) setting in the amp. I don't push the amp
>particularly hard - usually running about 500 w out. Our altitude here is
>about 7000 feet so HV may have a little more trouble with arcing than at
>sea level, but I'm not sure that this is a contributing factor.

Sometimes running less power aggrivates the situation. All exciters suffer from ALC response time lags, and are prone to power overshoot. This is too fast for some conventional PEP meters to read, but it is there.

For example, my IC-706, when set for 10 watts, overshoots to 140 watts on some bands. My 751A, Yeasu 757 and 747, and TS 950 all do the same. The TS 950 overshoots to 300 watts on some bands at leading edges of speach, or the forst character on CW.

If the PA is not loaded correctly for the PEAK drive power (even though it is instantanious) the PA tank voltage will soar. It can rach a peak value much higher than expected, and cause the tuning capacitor or bandswitch to arc. Correct loading means the loading capacitor has to the peoper value for full peak drive power. This is open much further than the amount that

gives you proper sustaned key down output power.

Another cause of this can be arcing elswhere in the system that "unloads" the tank.

>Well, as you may have gathered by now, it has started arcing again. I'm
>very careful to tune it into a nice low SWR load (G5RV + tuner or a 5 el
>log periodic), but I have problems with arcing at full output (~600 w) on
>160m and somethimes the higher bands (15 and 20 in particular).

I think you are tuning the PA wrong. If you tune it for less than full peak drive, you will be open for this problem. It also coud be the relays are not closing in the correct sequence.

SWR has nothing to do with this, as long as the tank adjusts correctly into the load and the SWR does not change during operation.

>I also found earlier that trying to use SSB on the SSB HV position would
>almost invariably cause arcing so I don't even try to use the higher
>voltage settings. I can always tune it up successfully at low power 200
w
>or so, but then why bother with an amp?

If you are tuning up at 200 watts, you are asking for trouble.

So the following questions come to mind:
>1) am I "arcing" or suffering from VHF parasitics? How can I tell the
>difference?

If you have VHF parasitics, they will be there consistantly. You can test for them by unterminating the PA (no input or output connections) and closing the relay. Use the highest HV setting and if you can boost the line voltage 10% or so by all means do it.

Rotate the tuning and loading controls, and bandswitch through their ranges while watching the grid and plate current. If the PA does not oscillate, it will certainly be stable with a load on the input and output.

>2) I haven't suffered (I think) any damage to tubes or resistors or other
>components in the TL922 (yet) - should I be on the lookout for other
>damage? What should I look for?

Nothing else at this point.

>3) Can this problem be aggravated by RF in the shack? I have a modest
>amount of it I'm sure...

Yes, because that will destroy ALC action and cause severe power overshoot from the driver.

>4) Should I pass on the TL922 and buy a more modern design? If so, what
is
>the recommendation?

The TL-922 is fine. Please describe HOW you tune it up. That would help.
What is your exciter?

They are here at last!

Now you can see what real DDRRs looks like.

You can also read about VE2DLJ tests and QSOs using
these DDRRs in the 75m DX Windows.

If you work DX on the low bands you certainly know the big guns
from VE2. Wonder what they use ? Check the pictures and you will
understand.

Report of the comparative tests between all sorts of Low Band
antennas (beam, rot. dipole, 4 square, wire beam, DDRRs, K5RP, etc)

3389. TL-922 Arcing/Oscillating? Help w/Diagnosis?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-29 00:00:00 UTC
From: "David B. Holtkamp" <holtkamp@roadrunner.com>
Message-ID: <01bbde0e$99e12c40$8b6d3bc6@holtkamp.roadrunner.com>
Source record: 100193

I have a several year old TL922A (mod for 10 m) and I've been having some trouble with it arcing (or oscillating - can't tell which). The details are in the next paragraphs, and I'd appreciate any help/suggestions on what to try next.

When I got the TL922 (from a silent key's estate), I noticed that the plate capacitor exhibited arcing damage - the position corresponded to a lower capacitance setting (little capacitor area active). The arcing had pitted and melted part of one of the plates (the fixed position one). I cleaned it up as best as I could (filed off, smoothed and straightened the plates, etc.) I used it for several more months and then it began arcing more or less steadily whenever I tried to tune up. I usually operate SSB with the HV setting on the lower (CW) setting in the amp. I don't push the amp particularly hard - usually running about 500 w out. Our altitude here is about 7000 feet so HV may have a little more trouble with arcing than at sea level, but I'm not sure that this is a contributing factor.

I replaced the tuning cap with a new one from Kenwood (~$120!!) and hoped that my problem was solved . I figured that the arcing was due to surface roughness and pitting that I really couldn't fix and I hoped that the new one would solve my problem.

Well, as you may have gathered by now, it has started arcing again. I'm very careful to tune it into a nice low SWR load (G5RV + tuner or a 5 el log periodic), but I have problems with arcing at full output (~600 w) on 160m and somethimes the higher bands (15 and 20 in particular).

I also found earlier that trying to use SSB on the SSB HV position would almost invariably cause arcing so I don't even try to use the higher voltage settings. I can always tune it up successfully at low power 200 w or so, but then why bother with an amp?

I've seen AG6K's material on his web pages (Thank you!), but I'm not sure that VHF parasitics are the cause of my problems (although they may very well be!). I've looked elsewhere on the web with little luck (so any pointers to other sources would be appreciated).

So the following questions come to mind:
1) am I "arcing" or suffering from VHF parasitics? How can I tell the difference?
2) I haven't suffered (I think) any damage to tubes or resistors or other components in the TL922 (yet) - should I be on the lookout for other damage? What should I look for?
3) Can this problem be aggravated by RF in the shack? I have a modest amount of it I'm sure...
4) Should I pass on the TL922 and buy a more modern design? If so, what is

the recommendation?

Thanks in advance for all your help!!!

Best regards,

David Holtkamp (K5KH)

PS Sorry to repost, but I was afraid that the Subject field was messed up.

Hello, David.....
The breakdown voltage of the 922's tune capacitor is about double the HF peak voltage encountered, so HF breakdown is quite unlikely, even at 10,000 feet altitude. However, if the plate that is arcing is bent out of alignment, HF arcing could certainly occur.
>
> So the following questions come to mind:

> 1) am I "arcing" or suffering from VHF parasitics? How can I tell the
> difference?

If you have a broadband 2-meter field strenth meter, place it near the 922 and see what happens when you see or hear the arc. The 922 typically oscillates around 140MHz, so a 2m field strength meter may detect the parasitic oscillation. If you have a neon lamp, place it near the anode circuit. If the glow is orange during the arc, the arc is probably HF-related. If the glow has a purplish tinge, then the arc is probably VHF-related. // If you are not sure if the 2m field strength meter will respond to the parasitic frequency, unplug the 922 from the mains, wait one minute for the hv filter caps. to discharge, using a dipmeter, measure the VHF resonance at the rear of the round, white DC blocking capacitor t the rear of the tune cap. The dip should be rather sharp and well defined. With the dipmeter oscillating at the freq. of this resonance, couple the dipmeter to the field strength meter to see if it responds.

> 2) I haven't suffered (I think) any damage to tubes or resistors or other
> components in the TL922 (yet) - should I be on the lookout for other
> damage? What should I look for?

The bandswitch contacts for the 80m and 160m tune padder caps, as well as the 10m and 15m tank inductor bandswitch contacts tend to arc and vaporize. (A photo of a crispy-crittered 922 bandswitch appears on page 33 of "Parasitics Revisited" in the October 1990 issue of QST.) To check for burned contacts on the bandswitch, remove the die-cast right side of the 922's cabinet with a 5mm allen wrench. // The zener diode sometimes shorts. // The grid and 'plate'(anode) current meter shunt resistors, as well as the meter movements, can sustain damage. If you don't have back to back 3A diodes across the meter movements, you might consider doing so. // During a VHF parasitic, a large pulse of current typically flows in one or both of the 1mH grid chokes. The current pulse appears to be very short, so no brief that no overheating is evident. Check the chokes with an ohm meter. Occasionally, the sections of the choke implode on each other and they will be bunched together at the center of the choke body. in such cases the choke tests open.

> 3) Can this problem be aggravated by RF in the shack? I have a modest
> amount of it I'm sure...

I don't think so.

> 4) Should I pass on the TL922 and buy a more modern design? If so, what is
> the recommendation?
>
I would not give up on the TL-922, David. It has some easily-fixed problems that you can correct if you can solder and follow a diagram. IMO, the 922's mechanical design is excellent.
A modern design is apparently not a panacea. New amplifiers are not quite as trouble free as their manufacturers would like for us believe. One such amplifier is touted as being like a Cadillac. Have you spoken with owners of recent vintage Cadillacs? I have, and most of the owners reported

problems with the electrical system. About one third of the owners of such amplifiers that I have spoken with have had problems that were apparently not their fault.

If you would like to read a general discussion on amplifier design, see the January 1994 issue of QST magazine. The article is titled "The Nearly Perfect Amplifier."

BTW, there is a discussion about VHF parasitics taking place on the 'Good source of amplifier tips' thread on this newsgroup. A proposal: I send you a low VHF Q parasitic suppressor retrofit kit for a 922 at no cost to you. After installing the retrofit kit, you can report whether or not the arcing at your 922's tune capacitor abated or continued, as the case may be. // IMO, it is risky to operate an amplifier that exhibits intermittent tune capacitor arcing. .

NOTE---- David: the above offer is immediately null and void IF you are one of Tom Rauch's brothers-in-law.

Message-ID: <329F4FE3.1B94@worldnet.att.net>
Source record: 100199

Here's a really easy way to produce exceptionally professional looking front panel graphics for your next homebrew project.
Use your favorite computer presentation or paint program to design the front panel on your computer (I like Microsoft's Powerpoint, but there are many others that do a fine job). Use fonts, shading, and color to get just the right look. Use your inkjet color printer to print the newly designed graphic onto ordinary paper. Laminate the paper printout using clear adhesive backed vinyl laminating material which is available at any office supply store. Cut out the graphic to fit the panel. Apply a light coat of aerosol adhesive (also available at your office supply store) to the surface which will receive the graphic, then apply the laminated graphic and gently rub the entire surface using a soft cloth to ensure a good bond. Trim off any excess material using an exacto knife.

This method produces very high quality, durable front panel overlays without the mess and frustration of paints, decals, or rub-ons.

Mario's solution never made it my news server, but Mario IS mathematically
correct according to what I read in the Will's archive---provided that the
currents are 90 degrees out of phase.. I was wrong for not considering
that the currents are out of phase. Comgrats, Mario. I am surprised that
one of the "recognized amplifier experts" didn't catch my error. (see 9/94
QST, page 71 column 3)

However, in actual practice, the currents are somewhat less than 90
degrees apart due to the intrinsic L in the suppressor resistor, Rs, and
due to the intrinsic VHF R in the suppressor inductor, Ls. For Rs, the
resistor we use in our retrofit kits has around 18nH and 30 ohms of R. At
100 MHz 18nH has 12 ohms of reactance. Thus, the I phase angle in Rs is
arctan 12/30= minus 21.8 degrees at 100MHz. The I phase angle in the
inductor is anybody's guess, but minus 80 degrees is probably close.

Since we don't know the phase angle between the currents, perhaps the best
solution is to state the ratio of the currents. Thus, the ratio of the
currents through Rs and Ls is fairly close to unity. .... Any comments
Mr. Rauch?

Sorry for the error. Thanks, Mario

> sensitvity of such an antenna is affected both by number of turns and
> area of the loop. My question is, if you can't have both, which is the
> most important?

For a receiving loop, the voltage
induced by an E field is:

V = 2.Pi.A.n.E.Cos(Angle)/lambda

A Area
n Number of turns
E field in V/m
Angle angle between plane of loop and signal

If tuned (capacitor) multiply the above by Q
loaded Q of tuned circuit formed by antenna
and capacitor.

Depends of what you want to use it for, space
avalaible etc... as you can see from the formula
you can play on Area or Number but the more turns
the more difficult to tune at low frequencies and
find a suitable capacitor.

One of the best book for Ham radio I know is

Solid State design for the Radio Amateur
by Wes Hayward W7ZOI and Doug DeMaw W1FB

It covers a lot of basics Transmitter design,
Power amps, VFOs, Mixers, Linears, CW, SSB...
Theory and "practice". Very good to learn,
not good if you want a step by step guide
to build a kit.

There is also Radio Frequency Design by Wes Hayward
which is also vy good (from what I hear) and more recent.

I think there was something about this type of lamp in the EMC pages of
Radcom a few months ago. I don't think they came up with a solution; the
supplier accepted them as being faulty, and made a refund.

Hi.
Excuse me for this unsolicited e-mail. I felt this was the
best way to inform you of our new service.

Here at PERSONALSEEK, www.personalseek.com, we've decided to build
another free international search engine,but this one is only for
commercial organizations. It is called BUSINESSEEK and it's absolutely
free. Try it for yourself at http://www.businesseek.com/

The goal of Businesseek is to allow the user to find a company, brand or
product quickly and easily. We will provide your company with a password
so you can update your data instantly and at any time that is convenient
for you.

We suggest you first use your native language .You can then submit the
same information in other languages depending on the markets that you
would like to serve. There are no limits regarding the number of
submissions. The information intake form will be available in english
spanish,italian, french and german.

We also have a COMPANY NEWS OF BUSINESSEEK section, where you will be
able to put up to 1000 text characters text giving news about your
company.You can describe new products or brands, new researches, etc.,
using the password we'll give you after you add your data.

To add your data, go to add in
http://www.businesseek.com/
After you have your password, you can acces our news service at
http://www.businesseek.com/business/news

Yours sincerely.

>Can I determine if a antenna is tuned and has the lowest SWR by listening >to the static on an unused frequency?

Probably not. The SWR is determined solely by cable impedance and the impedance presented *at the load end of the cable*. During receive, the *receiver* is the load presented to the cable. If the receiver presents a load grossly different from the cable impedance, SWR will be high, but this tells you nothing about how the antenna might behave as a load. And since HF receivers are typically voltage driven and not power driven, a mismatch here may give a stronger received signal rather than a weaker one. (This fact is often exploited in test equipment, where a very high impedance probe is used to get maximum signal readings. If the probe were of matched impedance, the signal would drop by 6 db. It would be said to "load down" the circuit.)

You can generally infer that the antenna is resonant when maximum band noise is received. Generically that says nothing about SWR, but can be useful information nonetheless. An antenna can be considered a parallel resonant circuit, so the voltage across it peaks at resonance. That won't necessarily mean it is well matched when presented to the cable as a load, however.

For example, if the antenna is a dipole, you know that it will have a feedpoint impedance near 50-70 ohms when resonated, so it may present a good load to 50 ohm cable. However, suppose the antenna is an end fed longwire. At resonance, it may present an impedance of several hundred ohms. That's obviously a poor match to 50 ohm cable, yet band noise on receive will still be at a maximum when the antenna is resonant.

Source impedance has no bearing on SWR, and during receive, the antenna is the source. During transmission, however, the antenna is acting as a load and does control SWR. During transmission, the impedance of the driving source, IE the transmitter, has no effect on SWR either. Only the load and the cable characteristic impedance determine SWR. This appears to be much misunderstood in the amateur community.

You *can* use a receiver to measure antenna impedance match, however, if you use it as the detector in a noise bridge. The noise bridge drives the antenna as a load, and the receiver then is used to indicate bridge balance, and hence allows you to determine the impedance of the load. But sky noise isn't a noise bridge, so it isn't useful for this purpose.

>>
>> Any sugestions would be appreciated.
>
>Couldn't you attach a VOX device from one transceiver's earphone outlet to
>the other's PTT & mic and vice versa?

Yeah, you sure can, and you don't need the vice versa, one radio acts as
the repeater receiver, the other as the transmitter. You only need cross
coupling for a crossband repeater where each side has to alternately
transmit. For ordinary in-band repeating, one VOX will do it. (It's
better to attach internally to pick up squelch break, IE a COR signal,
but the VOX will suffice for expedient use if you set VOX delay to a
long value, IE a long tail time for the repeater. Otherwise the repeater
may chatter in and out of transmit as the operators pause to draw a
breath.)

Just make sure the radios are well separated from each other, and their
antennas are even better separated from each other to avoid desense. A
few hundred feet horizontally, or 10-20 feet vertically, will suffice at
HT power levels. For mobile rig power levels, you'll need much more
separation, like a couple of miles horizontally or several hundred feet
vertically, or you can use some good cavity filters, IE like those in a
repeater duplexer. (You can just *use* a repeater duplexer, and that'll
let you use a single antenna too.) Remember, however, that the cavities
have to be precisely tuned to the pair of frequencies you're using.
You can't QSY without retuning the cavities.

Be sure to ID the repeater. Ideally, you'll have an IDer in the
interface, but you can also just make sure to transmit through the
repeater at least once every 10 minutes and ID yourself and the
repeater. Unless you want to include a remote control link (on
222 MHz or above), you'll want to operate the repeater under local
control. You may want to parallel in a local microphone so you
can use the repeater as your station too.

You can buy a commercial interface to do this (advertised in the
ham magazines), or you can easily build it yourself. It's a nice
little project to have in your emergency kit. Make up a bunch of
different cables to fit various brands of radios, and you'll be

able to quickly cobble up an expedient repeater from any pair of
radios which are at hand.

A final note here. While such an expedient repeater is pretty
simple to rig up, there are some caveats. Of course you have
to pick a pair of frequencies in the repeater subband to use
it, and you really need to be aware of other repeaters using
that pair (and adjacent pairs) in the area. Otherwise you may
set up an untenable interference situation. Using a rig which
offers crossband repeating is often a more viable approach
since separation issues become moot, as do interfacing issues.
But again, you have to be aware of other repeaters, this time
on *both* bands, to avoid causing (or receiving) harmful interference.

Join the ARRL. See their web page, www.arrl.org, for membership details. If you want overseas first class delivery rather than bulk mail, that costs extra. QST is now also available on newsstands, so you might check with magazine distributors in your area to see if you can get it that way (it costs more that way though).

>of the really good antenna .
>
>Would this work?

Yeah, it'll make a dandy oscillator out of the amplifier. :-)

What is the strongest signal your quarterwave on the amplifier
input is going to pick up? The 35 watts output by the amplifier
of course. So you get a nasty feedback condition.

>How about making a pipe to fit around the HT's antenna so I don't have to
>disconnect it?

Now this *may* work, if you get a good connection to the shield side
of the antenna connector. I doubt the impedance presented to the radio
would be anything near normal, however, and that might cause damage in
a radio that is not well protected against abnormal loads. Most HTs
are well protected against abnormal loads, however, because a rubber
dummy load often *is* an abnormal load.

If the pipe acts as a shield, IE is tightly bonded to the radio
"ground" connection and tightly bonded to the coax shield, and
the antenna couples capacitively to the inner conductor of the
coax, this may couple enough signal to drive the amplifier while
not picking up enough of the amplifier's radiated signal to cause
a feedback loop. This is pretty Rube Goldberg, however, and it
seems simpler just to connect the coax in the ordinary way.

Mr. Handy was talking about the suppressor inductor itself. I was talking about the suppressor inductor itself For a grid parasitic-suppressor, F. E. Handy recommends a100 ohm resistor and 10 ohms per foot resistance wire to wind the suppressor inductor. Quoting "The grid chokes in the photograph are most effective of all as a coil of resistance wire is used."

> That advice is, of course, correct, and is the
> way *every* parasitic suppressor is made today. Even yours. The resistance

This is the position of Mr. Rauch, who insists that insignificant VHF current flows through the suppressor L. Gary: Do you believe that insignificant VHF current flows through the suppressor L?

> Indeed, which is why there is a *paralleled* resistor across the inductor,
> to lower the suppressor's *VHF Q*, or more to the point, to increase the
> suppressor's *dissipation* at VHF. At *HF*, however, we want high Q so that

> we don't have attenuation of the *desired* HF energy.

I agree that we don't want HF attenuation. However, the additional loss created by a low VHF Q suppressor inductor is on the order of 1% at 29MHz and 0.2% at 14MHz. I found this acceptable because lower VHF Q suppressors eliminated occasional parasitic arcing in my SB-220 on 40m. If you feel that a 1% loss is unacceptable at 29MHz, then you should probably not be using lossy suppressor inductors. // Low VHF Q suppressors also eliminated the pecuilar double-peak in 40m output during tune-up. Other SB-220 owners have reported similar results in both of these areas.

Of late, I have seen plenty of seemingly-questionable VHF Q theories proffered hereabouts. If you have access to a dipmeter, Gary, you may (or may not) be interested in comparing the dip between a VHF suppressor L made from copper wire, and a VHF suppressor L made from nichrome resistance wire. If you are curious, but you need a low VHF Q suppressor to make the comparison, let me know for which amplifier. I will build a low VHF Q suppressor and mail it to you--free. The 55-cent stamp is on me. This offer is good whether or not you report your findings on this newsgroup.

Source record: 100138

Gary's posting on Shuttle problems was excellent.

A couple of points, though. The later quotes that he seemed to attribute to me were actually Tom's. Also, the discussions where the Thiokol engineers were "browbeaten" were, perhaps, not quite so one-sided as Gary implies. The engineers did not do as good a job making the case against a launch as they might have. One example: in presenting evidence meant to show a correlation between low temperatures and o-ring erosion, they presented only those cases in which there was erosion. However, the temperatures in those cases varied from about 53 degrees to 75 degrees. There was one incident of erosion in each of those seven missions, except for those missions launched at both the lowest and at the highest temperatures! (There were 3 and 2 incidents, respectively, in those cases.)

Had the engineers presented a chart including all missions, those with and those without o-ring erosion, the correlation between temperature and o-ring damage would have been much clearer. None of the flights NOT showing o-ring damage was launched below 65 degrees. However, of flights showing the erosion (i. e., the only ones used as evidence by the engineers in the pre-launch meetings), four were launched below that temperature and three above. The correlation they presented between temperature and erosion was hardly as convincing as it could have been, then.

Feynman thinks that various pressures led NASA managers to bend standards as they got away with anomalies. However, I don't think they realized the actual technical risks they were taking. No doubt Mr. Mulloy made it too hard for engineers to block the launch. However, one might wonder if part of his frustration was not due to the lack of a really convincing case against launch by the engineers in question.

By the way, in the "He Fixes Radios By Thinking" chapter I mentioned before, Feynman is a young kid who gets a reputation for being able to fix stuff. It's during the depression, as I recall, so a guy who has a terrible oscillation in the audio comes and picks Feynman up and drives him to his house. Feynman turns the radio on and hears the ungodly noises. So, he starts pacing back and forth until the owner says to him something like this: "What are you doing anyway? I thought I brought you here to fix the radio." Feynman responds: "I'm thinking!" Then he goes to the radio, switches two tubes and the oscillation is gone! The guy is suitably impressed and tells everybody "he fixes radios by thinking!" Feynman's explanation is in "Surely Your Joking, Mr. Feynman!" (which was the Princeton Dean's wife's response when he later asked for both lemon and cream in his tea.)

>Alberto.

I have made a dummy load for 425 MHz using a technique that you may be able to apply at 2.4 GHz. Basically you make a tapered water load. Take a section of waveguide several guide wavelengths long (or make a rectangular pipe the same size as whatever waveguide you are using -WR-340?) and mount it at a shallow angle, wide side horizontal. Fill it with odinary tap water to a level that fills the guide at the low end and doesn't overflow at the high end. If you are feeding the load with waveguide, you will need a bend to mate with the load section. You will also need some sort of moisture barrier the keep water vapor from condensing in the remainder of the waveguide. And, in order to remove 10 kW of power from the load you will need to circulate the water to a heat exchanger or run tap water and flow it into the drain. It wll take only a few gpm to keep the temperature rise reasonable. If you make the load too short you may not have a good VSWR. Also, the heating will be concentrated in the shallow end and you may not be able to remove it fast enough to prevent boiling.

Oh,yes. Put a vent pipe on the top side to prevent pressure build up. A 5 or 6" long piece of 1/4" ID pipe ought to do the job.

On the one I built, I was driving with coax at 425 MHz and coupled to the load with a stub antenna - just the center conductor extending into the wave guide a ways. I varied the length of the stub and its distance from the near end wall to get the best VSWR at the operating frequency.

Yuo can also use this load as a calorimeter to measure the power if you know the flow rate and the temperature rise, assuming you have

enclosed the load in styrofoam or something to prevent excessive heat loss to the air.

I also once made a load from a met garbage can filled with water, but it was not so broadband and was a bit harder to tune.

>I don;'t understand why it's so easily fooled.
>Care to elaborate a little of why clean sinusoidals
>are required ?

Sure, a clean sinewave is a single frequency, *any* other waveform
can be shown by Fourier analysis to be a combination of sinewaves at
a number of frequencies (which may be harmonic or non-harmonic). For
example, a squarewave is made up of a sinewave at the fundamental
frequency *and* all of the odd harmonics of that frequency. An AM
modulated signal is made up of carrier, fundamental modulation
frequencies, and their products, the sidebands, none of which are
harmonically related.

With any waveform other than a sinewave, the counter can lock to
any of the sinewave components making up the signal, depending on
a number of variables which aren't always under your control.

>
> The point remains what can you possibly do with a grid dip meter Rich?

I'm trying, I'm trying, but the guy with the AL-80 keeps stalling and
stalling, and nothing happens. The nice thing about a dipmeter is that it
does not require a physical connection to the circuit under test--as is the
case with other types of test equipment.

> It won't tell you a thing about the impedance of the system, other than
> reactance crosses zero at some frequency near the dip. Big deal.

If it's not a big deal, why not use your dipper to find the anode's
resonance point in the AL-80? If I sink, score one point for Mr. Rauch.

> Why waste time with a useless exercise.

Try me. I will be as brief as possible.

snip

Thanks, Tom. BTW, what is a "physic ability".
The reason I had to guess at the 160 figure is because somebody is
withholding the actual anode resonant frequency.

> > Using the formula XL=2*Pi*f*L,

OOPS. Big mistake Rich.

I am surprised that Tom didn't catch that one. The currents DO NOT total 21.1 mA because they are not in phase---as Mario, S53A, pointed out. Thanks, Mario.
However, the currents in Rs and Ls are not 90 degrees apart either. The L in the Rs I use is around 18nH. Thus, the current in Rs lags the voltage by roughly 20 degrees. Also, the intrinsic VHF R in Ls is not known. Thus, the VHF current in Ls is slightly less than 90 degrees behind the voltage. Another problem is that the intrinsic R in Ls, and the intrinsic L in Rs causes slightly less current to flow in each element than my current calculations indicated. All things considered, however, it seems logical that similar amounts of VHF current flow in Ls and Rs.....so there is still a hole in the opinion Tom Rauch has held since 1990--i.e., that no significant VHF current flows through a VHF parasitic-suppressor's inductor.
>
> You do not even understand the concept of current flow in a circuit with

> The Q is just barely over one. How much lower can nichrome make the Q go?
> What is the lowest practical or possible Q?
==========
OK, Tom, let's do Q.

A pure inductance with a reactance of 2 ohms is in series with a pure resistance of 10 ohms. What is the Q? // If the same inductance and resistance are connected in parallel, what is the Q?
==========
> You have claimed, before the whole world,...

Give us a break, Tom. The whole world? With all of the stalling that's going on, there might only be a few people tuned in. We still don't know the name of Mr. XXX or whether or not your AL-1500 amplifier design incorporates a VHF parasitic-oscillation suppressor. OTOH, the mysterious Mr. Miklos, who has never spoken with me, yet who reportedly refuses to speak with me on the telephone, perks up the plot a bit---even though it does sound like something out of a daytime television soap-opera. Are we supposed to pretend that Mr. Miklos can not hang up the telephone as need be if he speaks to me?

snip
> So now it is Mark Wilson also.....

Alas, even though Mark Wilson installed a low VHF Q parasitic suppressor retrofit kit is his once-squirrelly Alpha 77 amplifier, for some indeterminate reason, on page 74 in the September, 1994 issue of QST, he allowed Tom Rauch to say:

"The coil's reactance increases with frequency and at VHF most of the signal path is through the resistor. It is plainly evident that the dominant component at VHF is the resistor, not the coil."

I suspect that Mark's primary mistake was taking Paul Pagel out of the loop for the Sept. 1994 Technical Correspondence column. If Mark had given Paul the opportunity look this over, it seems pretty likely that Paul would have spotted the problem BEFORE it went to the printer. Another problem that might have been spotted was Fred Telewski's unenlightened statement about choke power supply filters being okay for use in linear amplifiers. Telewski's statement raised the eyebrows of all of the amplifier builders I know.

The pronouncement that, at VHF, no significant current flows in "coils" (inductors) is indeed specious. Your continued belief in this pronouncement is an enigma to me, Tom.

Rich,

Sorry to be so late in replying, but I had a massive disk
crash/corruption and I'm still trying to recover.

Thank you for your thoughts and suggestions on this matter and I will
happily try one of the parasitic reduction kits you are providing.

As we discussed, I will be sure to post the results of the installation
of this kit and be sure to let all who are interested know about the
progress!

Again, thank you very, very much for your help! And experience!

Best regards,

David (K5KH)

Hi Tom!

Thanks for your reply, and here's some more detail that might be helpful
>
> You can not fully restore a capacitor's voltage breakdown by this method.
> The voltage gradient at any point is determined by the radius of the
> plate, and any microscopic burrs and points.
>
> To give you an example, the plates of a capacitor are tumbled in
something
> as mild an abrasive as walnut shells for several hours to polish them.
> Even the slightest nick or scratch on the surface will lower the voltage
> breakdown.

Yes, indeed. I was initially thinking that it was my imperfect tuning cap
repair job that caused
it to start arcing again. But after I installed the brand new tuning cap,
I noticed that it would arc
on 160 m just as it had before (low HV setting - CW setting, near 600 w out
in CW, would
arc instantly if I set it to SSB HV setting and keyed the mike, even if it
didn't arc at
lower power/lower HV in CW).

I wonder if the new cap had the same flaws? Seems unlikely...especially
considering I ordered
it directly from Kenwood and paid top $$ (ouch!).

> Sometimes running less power aggrivates the situation. All exciters
suffer
> from ALC response time lags, and are prone to power overshoot. This is
too
> fast for some conventional PEP meters to read, but it is there.
>

Possible. I'm running a TS940S into it with ALC properly adjusted, etc.
Might it still
be overshooting?

>
> I think you are tuning the PA wrong. If you tune it for less than full
> peak drive, you will be open for this problem. It also coud be the relays
> are not closing in the correct sequence.

I am trying to follow the kenwood published directions ("Tuning up a
LInear

Amplifier" Kenwood newsletter Vol 2, issue no. 1). In it they recommend initial
tuning at an exciter of 50 w or less (I typically use 10 or so to get it close) then run up to 50
and retweek. A final quick tune up at something close to 100 w drive (ALC kicks in at about
70-80 w or so usually) often drives it into arcing.

>
> SWR has nothing to do with this, as long as the tank adjusts correctly
> into the load and the SWR does not change during operation.
>

Nope. SWR doesn't change - load/tune settings change slightly as I increase
the drive/output power but not by much.

> If you are tuning up at 200 watts, you are asking for trouble.

Why? I described above how that is the initial tune which is tweeked at nearer max power out. Is there something else here that I don't know about?

> If you have VHF parasitics, they will be there consistantly. You can test

>

I will try that and report what I see. Hope I don't hurt anything...<g>

> >3) Can this problem be aggravated by RF in the shack? I have a modest
> >amount of it I'm sure...
>
> Yes, because that will destroy ALC action and cause severe power overshoot
> from the driver.
>

How can I diagnose the RF overshoot better?If it is genuine RF power overshoot
from the Transceiver, then wouldn't it be there when I run it into an antenna directly?
Or would it only be there when going into an amp?

> The TL-922 is fine. Please describe HOW you tune it up. That would help.
> What is your exciter?

Hope I've answered these issues above. But let me detail my tuning procedure.

1) set antenna tuner close to good match conditions (from logs of previous good matches)
2) key TS940 alone at 5 w or so and tweek up the antenna tuner for 1:1 or darn close.
3) turn on amp with exciter at 10 w or so and tune quickly for max out with both tuning and load
caps in the 922.
4) recheck good SWR (minimize reflected power) with antenna tuner
5) turn up exciter to 50 w or so and quickly retweek the PA for max out
6) assuming I'm not arcing, edge up the exciter to 70-80 watts - at this point I generally
never have to readjust the PA or perhaps at most just a little. This is done quickly for obvious
reasons.
7) arcing sometimes occurs in step 6. Always CW setting on HV minimizes arcing. If I try the
SSB setting on HV I will always arc when I key the mike and utter a little audio.

Hope that is enough detail <whew> Thanks again for your help and suggestions!!!

I can pretty much believe that. After reading those it makes me wish
I had a daughter so I could forbid her to marry a lawyer. :)

>>Why is it that when you tell a 'joke' about an Irishman it is called
>>tasteless; when you tell a joke about a black it is called racist, and
>>when you tell a joke about a lawyer it is called funny?

Even though you didn't post this, I missed the original response so here
goes:

The reason it's funny is because by and large most lawyers are lower
than slime.

Tony

Any Ham, worth his salt, ought to have (at least) one copy of the ARRL
Handbook (formerly the Radio Amateur's Handbook).
This book has a treasure of electronics (RF and other) design theory and
projects. Regardless of many peoples feelings about the ARRL, as a whole,
they DO have some pretty handy books.
There is, also, a book out called RF Design that has quite a bit of
information, on a more "engineering type" scale that you might be
interested in. I'm flipping through my Electronics Book Club info, right
now, but can't find the book so I can't get the publisher or ISBN.
Why don't you locate the McGraw-Hill or TAB web pages and see what you
can find. I'd give you the URLs but NetScape crashed and lost all my
bookmarks and I haven't relocated those sites yet.
Hope this helps.
Randy.

Try joining the ARRL.
Their URL is "http://www.arrl.org/".
If joining is out of the question, they can probably respond to an
inquiry with a magazine outlet (somewhere) near you.
Currently, our local pharmacy carries QST in the magazine stand.
Good luck.
Randy/N7CKJ.

I have in my possesion a number of 5 terminal modules labelled 'OM322'
- there is also some sort of date/revison number 'B649'.

I guess they were made by Mullard/Phillips or similar, two terminals
on one side, and 3 on the other. The devices are a small encapsulation
bonded to a mounting tab.

If anyone could point the way to some data (if they are of any use for
TXers etc.) I would be most pleased.

Thanks,

Andrew

3451. 3-500Z amp schematic needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-30 00:00:00 UTC
From: nv0y@horizon.hit.net
Message-ID: <57o4eh$dd4@opal.southwind.net>
Source record: 100216

I am in need of a diagram of an amp using a single 3-500Z, GG, no tuned input. I built one several years ago and have since lost the ARRL Handbook (1960's vintage, red soft cover). I'm having some problems and need it for the specs for the output circuit. Any schematic meeting these criteria would be helpful. Thanks, Mike, NV0Y.

3452. Re: OM322 module - possible a V/UHF amp ? any details please.

>I guess they were made by Mullard/Phillips or similar, two terminals
Philips/Amperex.

>If anyone could point the way to some data (if they are of any use for
>TXers etc.) I would be most pleased.
Some of these were suitable as CATV amps....

OM322: Bandwidth: 40-860Mhz, 24V supply. Supply Current 60mA, 2
Stage, 15dB Gain, 7.0dB Noise Figure, 3tone output level for -60dB IM
= 103dBuV
Looks like it was inteded for CATV service by the inclusion of the
-60dB IM spec.
I only have the short form data on this device.
Try Philips databook, IC-16 , wideband amplifier modules.

3453. Free Boonton 250 (broken)

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-30 00:00:00 UTC
From: wa8mcq@u1.abs.net
Message-ID: <57o6qi$ff6@news.abs.net>
Source record: 100218

I picked up a Boonton 250 RX meter at a bargain price, "as-is" at a hamfest a few months ago. It was a good learning experience for $10, since it is fatally broken--one of the main tuning capacitors, the one attached to the terminals on top, had the ceramic frame cracked by a heavy object falling on it somewhere in the past. It is entirely beyond repair.

If anone wants the unit, they can have it free. The only catch is that you have to pick it up--these things weigh a ton! I don't know if it works otherwise--I was too lazy to check it out--but it at least appears to be physically complete and thus a good source of parts. There was no other apparent damage beyond the cracked capacitor body.

I'm located about halfway between the Washington DC and Baltimore beltways.

Greetings, electronics fans....

If you are interested in building some "kits" from artwork, schematics
and etc., then take a look at the (two) "kits" I have placed for
download on a web page.

At this time, the kits are:

A Direct Digital Synthesizer, which operates up to 20Mhz, and is
controlled by LPT1 on your PC.

A Phase Locked Loop circuit, using the MC145106
and MC1648 PLL IC's. It can operate to 225 Mhz.

A shareware program for printing HPG files to a laser printer.

The web page is: www.cyberramp.net/~bspeed/

3459. Re schematic drawing program

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-30 00:00:00 UTC
From: wa8mcq@u1.abs.net
Message-ID: <57of27$kt9@news.abs.net>
Source record: 100224

Someone recently endorsed the KeyCAD Complete program. I've been using it for a couple of years to draw the schematics in my column in the QRP Quarterly and it's a good-enough program, especially at the price. However, the electronic symbols library that came with it was, at least back then, quite horrible and minimal and virtually useless. I don't know if they have an improved library now or not, but the one in 1994 was nothing to write home about.

I made up my own library, which is quite easy to do once you get the hang of it, and it's better drawn and much more complete. For instance, as I recall, the original library had ONE transistor, a PNP, I think. My library has PNP, NPN, JFET, two types of enhancement FETs. It has a number of symbols that were simply not provided in the original.

If anyone wants to take a look at my KeyCAD electronics symbols library, do an anonymous to ftp.lehigh.edu, pub, listserv, qrp-l (that's a lower case letter L at the end, not number 1), and then I think it's under tools, where it should be fairly obvious which file it is. Ignore the very sort Keycad.txt file; it really should be erased and is meaningless. The drawing file is around 60K. Load it into KeyCAD, ignore the drawing that will appear on the screen, and open up and browse thru the library. Most, though not all, of my additions, are prefaced with MY, such as MYCAP, MYPOT, MYFET, etc.

Important note: all of my comments, and all of my files, apply ONLY to the DOS version of KeyCAD. They do NOT apply to Windows versions; I know for a fact that the two are completely incompatible with each other, since I tried swapping files with some folks who had the Windows version, and it simply does NOT work--totally different structures. (Neat programming concept, huh?)

I paid around $20 for the DOS version 2 1/2 years ago; the Windows was around $30. I don't know if either is still marketed, but there is a CD ROM floating around which contains the DOS version, at about $13, minus manual. You have to send them money if you want it; it did come with the old DOS version I bought, and all I can say for it is that, yes, it IS a manual :-) It IS more informative than the on-screen help, but still rather minimal and fairly unhelpful. I don't know if it's been improved since then.

In all, KeyCAD is a good, inexpensive program (though there are probably others out there in the same price ranges which are better). BTW, KeyCAD has been sighted over the years in places like Office Depot, Best Buy, Wal-Mart, Egghead, etc--widely available. [Usual disclaimers--no interest in the company, etc.]

A little trivia here--my mother was George Grammer's secretary during WWII (or was it just prior to), during which time she met my father, Arthur J. Stevens, Jr., who, fresh out of M.I.T., was doing research at Remington-Rand on early radar designs. She subsequently became the current Mrs. Stevens sometime in 1945. Prior to that event, she was Jane Guglielmetti, of Durham, CT.

She has always had the highest regard for Mr. Grammer, by the way, as an employer, and as an individual. But the, those New Englanders tend to stick together.

Always wanted to share this with someone.

Now, back to the action.

I wonder if the family isn't in cahoots on this - Grandparents file
bankruptcy, Homeowner's insurance pays, Everyone profits.
Get a few crapola TV show appearances & a book.
Grandparents now live high on the hog in retirement.
Children inherit estate.

So they say, well, let's at least get something positive out of
the bad situation, eh?

Probably how a lawyer's mind works.

If I had to guess, based on no other information, I would guess that this is a scheme to get around the inheritance tax, which will tax a bequest from the grandparents to the kids or grandkids, at a confiscatory rate of 45% if they have a sizeable estate.

On the other hand, tort damages for physical injury are generally excluded from taxes. Therefore, the unfortunate injury to the daughter may be a vehicle for all concerned to avoid the inheritance tax. (Or it may not be; I'm only guessing).

Sounds like a clever scheme, by a clever lawyer. The kind of lawyer people pay good money for.

There are other methods. If you want a front panel with scratch-proof
lettering in black and transparent, print to a PostScript file and
take that to a local print shop. They will put in on imagesetter
film (up to 2400 or even 3600 dpi). You can then spray-glue this
film on the front panel.

These films are also extremely useful when producing PCBs.

I'd use a 723, going through a bank of well heatsinked pass transistors.

At that current level, I might even use a switch mode regulator
(convert that voltage to current instead of heat).

Dear Forum Members:

I am looking for some quick ideas to build a C.W. 10 KWh, 2.4 GHz MW dummy load, perhaps you have some suggestions.

Any quick fix or hint would be much appreciated. I was considering building an oil cooled dummy load, using a tradiitonal UHF design as used in most amateur radio shacks, but I would like to hear your comments first, before I take the house down.

Thank you for your help.

Alberto.

For Sale:

Sunair GSL-1900A Kilowatt Linear Power Amplifier. Consists of the
LPA-1900A RF
PA and the PS-1900A power supply unit. This set easlily delivers full
rated
power on all bands. Asking price: $2000.00. I prefer pickup from my QTH
in
Sacramento, CA. If I have to ship it, you pay shipping from zip 95826.
The rf
deck will be about 90 lbs packed for shipping and the power supply will
be
about 150 lbs packed for shipping. (since UPS has a max weight of 150
lbs,
I may have to remove the choke from the power supply and ship
separately)

For those not already familiar with this unit, some specs from the
manual are
listed below.

Covers 1.6 to 30Mhz (continuous) in 8 bands.
Conservatively rated at 1Kw PEP for SSB,
1 Kw for CW, and 1Kw average for AM.
(the book says 300 to 400 for AM carrier only, then
limit the total power with modulation to 1Kw).
Requires 40 watts PEP input to drive to full output.
Automatic tuning (plate and load). Tuning time 3 seconds, nominal.
Uses 4CX1500B, Pi-L output network, and 50 ohm passive input
(no tuning needed for input).
Very low distortion.
Intermodulation distortion: better than -30 db
Harmonic distortion: better than -55db
Power supply strappable for 120 or 240v operation 50-60 hz.
and power consumption is approx 3Kw. (240v operation is
highly recommended and is current strapped for it).

A copy of the Operation and Maintenance Manual will be included. The
interconnect cables between the rf deck and power supply were not
available at a reasonable cost (Sunair wanted $1200 for just the cable
with connectors) so I made an easily restorable modification. The units
are in good condition cosmetically and fully operational.
Also, I have contructed an interface unit that works with my Yaesu
FT-747 for

operating the amplifier. It provides the remote power control, band selection,
and tune functions that would normally be provided a Sunair exciter. This is
included with the purchase of the amplifier. The interface unit can be easily
adapted to work with almost any tranceiver.

Please respond via E-mail to the below address.

For Sale:

4CX1500B/8660 and air system socket, $300 plus shipping
from zip 95826.

I have three of these sets.

They are pulls and have been tested in an operational
Sunair 1 Kw amplifier. Full power out, 160m thru 10m
into dummy load.

The sockets do not have any markings on them, but
after comparing them to the Eimac catalog, they appear
to be SK-800B sockets with 1500pf screen bypass capacitor.

Please respond via E-mail at the below address.

Thanks.

For Sale:

Sunair GSL-1900A Kilowatt Linear Power Amplifier Consists
of the LPA-1900A RF PA and the PS-1900A power supply unit.
This set easlily delivers full rated power on all bands.
Asking price: $2000.00. I prefer pickup from my QTH in
Sacramento, CA. If I have to ship it, you pay shipping
from zip 95826. The rf deck will be about 90 lbs packed
for shipping and the power supply will be about 150 lbs
packed for shipping. (since UPS has a max weight of 150 lbs,
I may have to remove the choke from the power supply and ship
separately)

For those not already familiar with this unit, some specs from
the manual are listed below.

Covers 1.6 to 30Mhz (continuous) in 8 bands.
Conservatively rated at 1Kw PEP for SSB,
1 Kw for CW, and 1Kw average for AM.
(the book says 300 to 400 for AM carrier only, then
limit the total power with modulation to 1Kw).
Requires 40 watts PEP input to drive to full output.
Automatic tuning (plate and load). Tuning time 3 seconds, nominal.
Uses 4CX1500B, Pi-L output network, and 50 ohm passive input
(no tuning needed for input).
Very low distortion.
Intermodulation distortion: better than -30 db
Harmonic distortion: better than -55db
Power supply strappable for 120 or 240v operation 50-60 hz.
and power consumption is approx 3Kw. (240v operation is
highly recommended and is current strapped for it).

A copy of the Operation and Maintenance Manual will be included.
The interconnect cables between the rf deck and power supply were
not available at a reasonable cost (Sunair wanted $1200 for just
the cable with connectors) so I made an easily restorable modification.
The units are in good condition cosmetically and fully operational.
Also, I have contructed an interface unit that works with my Yaesu
FT-747 for operating the amplifier. It provides the remote power
control, band selection, and tune functions that would normally be
provided a Sunair exciter. This is included with the purchase of
the amplifier.

3472. Suppressor calculations

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-11-30 00:00:00 UTC
From: s56a@s55tcp.ampr.ORG
Message-ID: <21170@s55tcp.ampr.org>
Source record: 100237

Rich, AG6K asked me to show the right mathematical formulas for calculating VHF suppressor values and I did my homework! To the best of my knowledge, this was not done before in the ham literature. I understand N7WS showed proper current distribution in parallel R/L circuit ahead of my KISS example.

#1.
Decide the frequency of potential VHF oscillations from known history of the particular tube or measurement data in real QRO circuit. Avoid the multiples of the highest operating frequency (in case of 30MHz NEVER tune suppressor at 90, 120 or 150 MHz). Let us take F=130 MHz.

#2.
Calculate the inductance value needed to resonate tube output capacitance in series with minimal variable tuning capacitor value at highest operating frequency. Let us suppose Cout=20pF and Cmin=20pF which gives C=10pF.

L=25330/C x F**2 (uH, pF, MHz) = 25330/10*(130*130) = 0.15 uH.

#3.
Calculate the reactance of L at the highest operating frequency.
Let us assume f=29 MHz and X=2*Pi*f*L = 27.3 Ohms.

#4.
Take a dumping resistor with a value at least three times higher than X.
Let us take 100 Ohms, but what is a power rating?

#5.
Assume we use two tubes for a legal 1.5kW RF output with HV >= 3kV.
Total RF current is Irf=P/U/sqrt2=1500/3000/1.41=0.7A.
This should be equally split to I = 350mA per tube.
We know that voltage R*Ir equals X*Ix and currents Ir**2+Ix**2=I**2.
Therefore Ir=I/sqrt(1+(R/X)**2)=350/sqrt(1+3.66**2)=350/3.79=92mA.
P=R*Ir**2=100x(0.092x0.092)=0.8 W

We should play it safe and take 2W resistor and IF it overheats, we are either tuned to harmonic frequency or have a serious VHF oscillations!

73 de Mario, S56A, N1YU.

P.S. Do NOT use high resistance wire for L as one is wasting ONLY RF energy without any effect on VHF! Dumping resistor does that job smoothly.

W8JITom, how is your cold?

3473. Ten-Tec 2 meter FM transceiver

If the R measures (no pun intended) more than a few ohms at VHF, does it seem likely that the conductive material is silver, Wes?

1200 baud is the standard for VHF packet. There is the rare 2400 baud,
but used mostly for dedicated links between 2 stations. 9600 has a wide
usage on 440, and I've even seen some 19200, but these require radios
either factory capable for 9600+, or modifications you perform to make
them 9600 capable. There is a 56K packet modem available now, but
without the local PBBS being on the same modem, you'll only be able to
use 1200 anyway.

Later,
Dave

: theory/construction of a temp compensated VFO. The schematic reminded me of a
: PLL with a feedback loop tied to a crystal oscilator. In his article, he made
: the statment that his VFO wouldn't have the extra phase noise that a
: traditional PLL has because of the loop. Can anyone explain this? I didn't
: think that the VCO wouldn't be effected by the locking loop.

A variactor tuned oscillator will have more phase noise on the output than
a well designed LC oscillator. Take, for an example, a synthesizer for
a 0-30 MHz receiver, covering the range with 3 different VCO's,
per the recommendations of Rodhe. Each VCO would cover 10 MHz of
freq with a voltage swing on the varicaps of perhaps 10 Volts, so
it would be 1 MHz/1 Volt, or 1 microvolt of noise would move the
freq one hertz. It takes a very good op amp, fed by very clean power
supplies, not to have microvolts of noise on it's output. Low freq
noise within the loop bandwidth will be mostly canceled by the PLL
(it can't cancel it all - it doesn't start to react untill it detects
a change has already occured), but higher freq noise components
above the loop time constants will not be canceled.

Source record: 100097

Hi Mario,

I'm trying to keep this in one thread.

You can test for resonances by adding a large self bias resistance between the cathode and chassis. That allows the tube to AGC itself without hard limiting.

The reason I've avoided the math analysis is because, as you discovered, many things go on at once. The equivalent series resistance needs to be large enough to dampen the series reactance of the anode lead over the range where the tube is capable of oscillating.

The goal is to make the anodes series impedance through the blocking capacitor and plate tuning capacitor as low as possible, while making the ESR as high as necessary to minimize Q in the frequency range of instability.

Make the resistance either too low or too high, and stability is compromised.

This topic is best covered in an article with drawings, rather than verbally. My point is this, the last thing in the world we want to do is make the anode leads more reactive, other than the single point where suppression device is located. A much larger reduction in Q is afforded when this goal is met.

It's a big series circuit path, and adding resistance in series with the primary HF path (ie the suppression "coil") does little to nothing to VHF or UHF Q. The total anode path inductance is comprised of much more than that little coil of wire in the suppressor.

73, Tom

Hi Rich,

You see, you and I do agree on some things.

In article <measures-ya023180000112960749010001@news.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

>Amen to that Tom. When I said that ALC-systems in transceivers had a
>problem with attack-overshoot in "The Nearly Perfect Ampilifier" (QST,
>1/94), I was criticized for it by Fred Telewski, WA7TZY, in the 9/94 QST.

>Telewski said "Measures' comments about ALC being generically flawed are
>inappropiate." // Any comments, Mr. Telewski?

No, Fred was incorrect. He has little experience with HF transceivers, or
he would have known better than to make a comment like that. Virtually
every HF transceiver I have owned or looked at has this problem, and the
Kenwood are among the worse of the lot.

ALC and a modern exciter's power control are only, in my view, last ditch
methods of reducing power. My IC-706 spikes up to 150 watts on 40 meters
when the output is set for ten watts. My TS-950 over 250 watts!

> However, I have not measured the amount of overshoot you claim. The
>highest overshoot I have measured from a Kenwood radio with my Hewlett
>Packard oscilloscope was 45% in terms of power, or 20% in terms of RF

of
>300w, the two 3-500Zs would saturate at about 150w drive and the extra
>drive would not significantly change the peak voltage across the 922's
>tune-capacitor.

The 3--500Z's do not saturate until they reach a peak anode current of
perhaps 10 amperes per tube. That means the tubes give the tank a big hard
"yank" and allow it to overshoot.

Rich, I've heard you say that before. The dact is a 3-500Z can output 5-10
kW before saturating.

You have no problem blaming VHF parasitics for high power levels, yet you
claim saturation with 150 watts of drive. That sounds very inconsistent to
me.

>Prior to 1986, I used to wonder too, David. Eimac's Mr. Foote seemingly
>sent me off in the right direction. Hmmmm. I am still wondering why
>Eimac's Reid Brandon, W6MTF, told QST's Paul Pagel that Mr. Foote was NOT
>AUTHORIZED to release such information to Mr. Measures?

Foot was only a guy assigned to answer customers letters about tubes, he was not a design engineer any more than Orr was.

>My triggered-sweep oscilloscope works fine---providing one sets the trigger
>level high enough to begin the sweep only at abnormally high RF peak output
>voltages. With a storage scope, you would have to use the same trigger
>setup procedure---however, with a storage 'scope the image lasts all day
>instead of a second or two.

You can still miss the crest Rich. It is better to trigger the scope from the signal source driving the microphone, and freeze the first several dozen cycles of RF.

I use a sample and hold meter with a ten microsecond storage sample time. It has a decay time > ten minutes.

Anyone thinking because they set the rig to "X" power it only outputs that much, or that ALC and power control reduction is a good way to eliminate splatter, is mistaken. The WORSE thing to do is reduce the power via those means. that virtually guarantees splatter, power overshoot and PA arcing.

Here we finally get past the Quackery and Voo Doo, and to the heart of the matter.

In article <57rsj0$e6s@dallas1.connect.net>, philk5pc@connect.net (Phil Clements) writes:

>Doesn't the high resistance wire act to limit the terrible ALC overshoot
> found in modern-day exciters, protecting the tank capacitor and
> bandswitch et al in the same manner as a series R in the H.V. lead
> protects tubes/components in case of flashover?

It does limit the voltage excursion by reducing Q at the operating frequency Phil, but it also lowers desirable performance even more. "De-Q'ing" from the addition of a lossy conductor in the primary HF path results in a non-linear with frequency Q reduction. The loss of Q peaks in the upper HF region, and is insignificant below perhaps 10 MHz and above 100 MHz.

A more correct cure, in my view, is to properly load the PA, install a spark gap across the tank cap, and eliminate the transcient in the exciter. Learning to operate the PA properly means more than anything. By properly I mean the PA should be loaded heavy enough, and if the exciter is too powerful an unbypassed series resistance should be used at the cathode of the tube.

This resistance increases negative feedback as well as attenuates excessive drive power. This allows the exciter to be operated close to its' rated power, and reduces IMD and ALC overshoot.

>I am not even qualified to shine the shoes of the participants in
> "good source for amplifier tips"...(flunked H.S. math) but I am
> certainally learning plenty via that thread!

I wear tennis shoes, even with a suit. If we can cut the persoanl attacks and frivilous questions down, this thread would be more useful. No one that I have met in life knows everything about everything, or even about a single subject. Nor is there ALWAYS just one simple solution to any or all problems.

Think about that.

Not saying that you want to 'Slum it' there is always the option of pulling one out of a used CB..

That's what I've done.. some are kind of attractive..

Jim..

3488. IC-27H Tone Encoder

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-01 00:00:00 UTC
From: robmitch@vaxxine.com
Message-ID: <32a0caae.1499933@news.vaxxine.com>

Does anyone have any information on how to modify a ICOM
IC-27H to enable the subaudible tone encoder to tramsmit on simplex as
well as on duplex.

Any assistance would be greatly appreciated.

3491. Good source for amplifier tips

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-01 00:00:00 UTC
From: stoskopf@tri.NET
Message-ID: <32A0F185.2392@tri.net>
Source record: 100164

Just discussed this supressor bit with an experienced Collins TX engineer. Found it amusing. They had a 10 KW HF rig that had an inch wide by three inch aluminum strap from the tube to the tuning capacitor. Mounted on the strap were two noninductive resistors side by side (parallel) mounted along the strap. Everyone looking at the amp wondered why they shorted the resistors.

Apparently you build the amplifier, then figure out where the parasitics are and do what it takes to get rid of them. Seems a bit empiric for todays models, but doubtlessly effective. This is the limit of my information on this.

3492. PLL's

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-01 00:00:00 UTC
From: zclobes@southwind.net
Message-ID: <57qrpb$ag8@opal.southwind.net>
Source record: 100165

I was reading an article in the latest copy of QST covering the theory/construction of a temp compensated VFO. The schematic reminded me of a PLL with a feedback loop tied to a crystal oscilator. In his article, he made the statment that his VFO wouldn't have the extra phase noise that a traditional PLL has because of the loop. Can anyone explain this? I didn't think that the VCO wouldn't be effected by the locking loop.

From: gnbc@alpha.wcoil.com
Message-ID: <57qtfc$lui@tofu.alt.net>
Source record: 100166

Hello gang,

I tried to post this on my other server, and it apparently did not make it out for some reason, so let me start again.

I'm looking for a PL dectector unit, (prefer commercial assembly) for installation in a repeater system. I have tried the Hamtronics, which I was disappointed in the quality, and the Selectone ST-139 which I had some problems with, so I would like to see what else is available.

Needs are... must fit into a 2" x 2" x 1.2" space, and powered by +12vdc. 1). Needs to pick up quickly, and needs to drop when the tone goes away. 2). Must give either a +5 volt logic level to the controller or have a common collector output which I can use with a 12vdc reed relay to provide the signal back to the controller. (Reed relay takes about 34 mills at 12 volts). 3). The PL at the discrim point is 2/10ths of a volt p/p

I would prefer something built as I don't have the time right now to experiment with this and that, and especially trouble-shoot. I need to get the repeaters on the air.

If anyone knows any manufacturers that build a kit that will sence 100 hz PL, please E-mail me at w8hdu@wlio.com or gnbc@alpha.wcoil.com

Hi Dave,
In article <01bbdf11$127339c0$826d3bc6@internet.roadrunner.com>, "David B. Holtkamp (K5KH)" <holtkamp@roadrunner.com> writes:

>Possible. I'm running a TS940S into it with ALC properly adjusted, etc.
>Might it still
>be overshooting?

It absolutely is, the Kenwood I have overshoots into the 250-300 watt range on some bands. Unless you load the TL-922 to accept that amount of drive power, the tank voltage will soar during leading edges of speech or initial key closure.

Remember the power control is via the ALC system. The contol voltage is derived from an RF output detector that feeds a voltage comparison system. When the output power detected by the detector if the detector voltage exceeds a reference voltage, ALC is developed.

When the rig is at rest, or on receive, the ALC voltage is at zero. The TX system is at full gain. It takes several RF cycles before the ALC voltage can climb and limit drive.

>> I think you are tuning the PA wrong. If you tune it for less than full
>> peak drive, you will be open for this problem. It also coud be the
relays
>> are not closing in the correct sequence.
>
> I am trying to follow the kenwood published directions ("Tuning up a
>LInear
>Amplifier" Kenwood newsletter Vol 2, issue no. 1). In it they recommend
>initial
>tuning at an exciter of 50 w or less (I typically use 10 or so to get it
>close) then run up to 50
>and retweek. A final quick tune up at something close to 100 w drive
(ALC
>kicks in at about
>70-80 w or so usually) often drives it into arcing.

I'm not surprised by this. Does Kenwood warn you to overcouple the PA slightly before advancing drive? If not, they should. This problem is compounded by the fact the 940 certainly has power "overshoot". The load control should always be operated beyond the setting where maximum output occurs, and you should never depend ALC to keep the power reduced. The ALC/ power control system is just too slow.

Ameritron has problems with 940's knocking out the gate junctions of FETs in a FET amp for this same reason. The cure is to add an external adjustable bias supply to the ALC control input, and set that voltage so the power is limited to 80 or 90 watts peak. Then the normal power control is used to reduce it further. That limits the overshoot.

>> If you are tuning up at 200 watts, you are asking for trouble.
>
> Why? I described above how that is the initial tune which is tweeked at
>nearer max power out. Is there something else here that I don't know
about?

The way a PA tank functions requires a lot of time to explain in detail, but let me try a brief explaination.

The tube is a variable resistance that "pulls" on the tank to get the voltage swinging. But it is important to remember the tube is a variable resistance in series with a "diode", the anode cathode path form the diode.

Energy is stored in the tank and related components (like the plate choke), and that energy is like a pendulum.

If the tank is not transferring all the energy (caused by the pull of tube) the energy builds up in the tank, and voltage soars. Unless something dissipates this energy, it will reach levels that cause components to break down.

When you load the tank "lightly" (too much loading capacitance for the amount of "pull" provided by the tube) the Q (energy storage ability) is increased. The eccessive drive power pulse comes along and makes the tube give the tank a real hard yank, and the voltage overshoots. The sudden surge can exceed the rating of the switch or capacitor, and cause an arc. Once the arc is established, the ionized path continues to arc even after the leading edge pulse is gone.

You are using the 922 at the worst possible condition for arc prevention when you run low power at high anode voltage.

>> >3) Can this problem be aggravated by RF in the shack? I have a modest
>> >amount of it I'm sure...
>>
>> Yes, because that will destroy ALC action and cause severe power
>overshoot
>> from the driver.
>>
>
> How can I diagnose the RF overshoot better?If it is genuine RF power
>overshoot
>from the Transceiver, then wouldn't it be there when I run it into an
>antenna directly?

Yes, but you need a storage scope or a very good very fast peak reading meter. Even a Bird 43P is on the slow side for this. There is no doubt you

have the problem, because I've yet to see a modern rig that doesn't.

Do you have a fast peak reading meter, or a storage scope? If you don't have a fast peak reading meter, how do you know you are driving the 922 correctly at the power you loaded it up at?

>Or would it only be there when going into an amp?

Nope, it's there all the time. The power on your rig will climb up nearly to the value it outputs when the ALC is disconnected (internally). That is a few hundred watts. It will do that regardless of the power setting of the rig. Let's say that level is 200 watts.

Tune the PA with 50 watts, and you are spiking the PA with four times the loaded power once in a while on leading edges. Tune the PA up at 120 watts drive, and the sipe is still 200 watss but now the PA is loaded with a much lower Q and less tank voltage overshoot.

> Hope I've answered these issues above. But let me detail my tuning
>procedure.
>
>1) set antenna tuner close to good match conditions (from logs of
previous
>good matches)
>2) key TS940 alone at 5 w or so and tweek up the antenna tuner for 1:1 or
>darn close.
>3) turn on amp with exciter at 10 w or so and tune quickly for max out
with
>both tuning and load
>caps in the 922.

Never do that. It''s a wasted step, and asking for trouble. Record the load setting at higher drive levels and always preset the load control to those settings. It will be very repeatable. With ten watts of drive, the load control will be very close to closed if not closed. That means maximum Q and voltage in the tank, and a chance of damage.

>5) turn up exciter to 50 w or so and quickly retweek the PA for max out

Ouch. Now the PA is set for 10 watts and you drive it with 50 while you retune!

>6) assuming I'm not arcing, edge up the exciter to 70-80 watts - at this
>point I generally
>never have to readjust the PA or perhaps at most just a little. This is
>done quickly for obvious
>reasons.

>7) arcing sometimes occurs in step 6. Always CW setting on HV minimizes
>arcing. If I try the
>SSB setting on HV I will always arc when I key the mike and utter a
little
>audio.

I'll bet it would, the radio is jamming the amp with a few hundred watts on leading edges, and the amp is loaded to accept 50 watts or so! It's better to run the load control too heavy, and then back up to near full output.

Now if you put anything in the tank that dissipate energy, it will lower the voltage. Nichrome will have this effect to a limited extent, because it lowers the HF Q and reduces energy storage in the tank.

You could also add a spark gap across the plate tuning capacitor, so it arcs before the tuning cap. Say something made from a very hard metal like stainless steel.

Aside from that, I'd buy a good peak reading meter (if you don't have one) and OVERLOAD (the loading capacitor set slightly beyond maximum output) the PA when tuning before ever appling full power or voltage.

The worse thjing I can think of for both splatter and arcing is to set the loading cap too light, and to throttle back the 940 without using external bias on the ALC.

Doe this make sense, or do I need to explain some areas better?

73 Tom

From: horizons@comm.net
Message-ID: <horizons.48.00C35635@comm.net>
Source record: 100170

Greetings all;

I am currently writing an article for a ARES Internet News Letter on the effects of tidal surge, high winds, tornados and over usage of these systems in the event of a catagory 4 or 5 hurricane striking the US. As I live in New Orleans, I have not experanced a major hurricane sense Camile in 69 and Betsy in 63. Neither of these storms had a direct impact on the city. Even if they had, the types of communications that both civilians and goverment where only a dream or thought in someones mind.

I am looking for any information from those that have been in HAM radio or involved with local or state goverment communications in an area hit by a major storm in the last 10 years or so. I could really use thyeir input in order to make sure what I write is as close to the truth as possible. What I need to know is:

1. How badly where the systems jammed before the storm hit?

2. What was communications like during the storm?

3. How many different types of systems where down after thye storm pasted. ie; Commerical, Goverment and Amateur?

4. How long did it that to get these systems back operational?

5. What form of communications where use after the storm, and before normal communications where restored?

6. What lessons where learned by both those that use VHF, UHF, 800 & 900 trucking and Celluar?

The answers I reveive could help other areas prepare for the possibility of such a storm. As for New Orleans, we really need a wake up call as many of those living here have never been in a severe hurricane ands think fror whatever reason God will protect our city. So, if any of you could help enlighten me as to what occured in your area, I would be most grateful.

Please send all answers to: horizons@comm.net

Hi All!

I am designing a converter for the 432 to 438 MHz Band.As I am not very
experienced at uhf,I would appreciate any comment regarding my design.For
the local oscillator of the converter I would like to use a computer Crystal
oscillator at 25,175KHz as the base,than multiply it 2x-3x-3x to 453MHz.
The incomming signal is to mix in the mixer (NE602 or diode ballanced mixer)
with the local oscillator(453MHz).The output will be connected to an ICOM735
receiver tuned between 18 and 21 MHz.Needless to say the input will first be
amplified in a BF981.
Will it work ? NE602 or Ballanced SBL-1 will work better?any other sugestion?

Tom, W8JI had my callsign as S59A and now Rich, AG6K comes back with S53A while I am caught in the middle as Hollywood related S56A :-) How can I expect any answer to my herioc attempt to do suppressor mathematical calculation when the top USA experts can't even get a single number right :-)
N0UU note on commonsense Collins approach regarding potential VHF oscilations on 10kW TX confirms my feeling that suppressors are actually pain in the back! W8JI stated that dumped VHF oscilations happen when we switch bias plate current to the tube but that might be the case ONLY if switching time is in tens of nanoseconds range in order to excite >100MHz oscilations. Every other steadystate phenomena can be related to the RF driving timing and harmonics involved with B class tube operation.
Once I did my math and realized that resonant frequency of suppressors changes about 50% with the value of tuning capacitor in series with tube output capa-citance, I begun to doubt the value of VHF protection against accidental harmonic resonances.
However, I don't like to repeat my destructive test of SB-220 by replacing both suppressors with thick wires as they survived for 20 years including RTTY torture. I am only having problems with poor heather pin soldering on my new Chinese 3-500ZG from RF Parts but I am so far away from Hollywood that I do not consider returning them in waranty :-)

One of the most inovative suppressors I have ever seen is a current
model made by Henry Radio for the 3CX3000A7. It is a 1 inch wide,
5.5 inch long hard-drawn copper strap bent into a 1 turn coil, 1 inch
in diameter. The strap is then coated with chrome plating (like car
bumpers used to be) until the resistance of the chrome reaches the
necessary R to meet the design specs. for its application. This
eliminates the need for big parallel resistors accross the coil,
nichrome wire, (or strap, in this case) and will certainly handle any
power on H.F. that the tube is capable of! My meager test equipment
(Autec RF-1 and R.S. DVM) show that the L is about .34 uh @ 28 mhz
and the R of the chrome is 25-35 ohms. I have one of these hanging on
my wall to remind me to strive for simplicity and inovation in my
design work. Nice going, Henry!! (((73))) Phil, K5PC

(or strap, in this case)

I heard that at the time of launch of Mission 25, there were some layers of
rapidly moving air at high altitude due to the weather front that had just
passed through and delayed the launch. Anybody who has done much flying
knows what passing through these layers is like. Since Mission 25 passed
through such layers, extra vibrational stress was placed on the SRB joints.

Congrats, Gary. You guessed correctly. I can still remember the tobacco
company executives testifying before Congress, who, to a man, in sworn
testimony, said that nicotine was not addicitive.

A friend of mine was addicted to heroin. He smoked cigarettes.
Eventually, he was able to kick the heroin habit. However, he was never
able to kick the nicotine habit. .

BTW, I used to occasionally catch a ride to work in a Ford Pinto.
I enjoyed your comments about politics and the Utah vote in Congress.
Term limits might help.

Hmmm. Sounds like a Henry 8K. It's been a while since I saw the inside of
one of these, but I doubt that the suppressor is chrome plated. I
think it's polished silver.

Also, your measured inductance seems awfully high. That's probably
about 15-20% of the tank inductance.

BTW, I was trying to help my friend re-engineer this thing to stop the corona
and arcing problems with the homemade relay contacts used to switch the fixed
tank capacitors. Some good old corona reduction techniques like smoothing
corners and increasing spacing did the trick. No nichrome was required.

Thanks for the reply, Tom. Here are some comments and further questions:

> Remember the power control is via the ALC system. The contol voltage is
> derived from an RF output detector that feeds a voltage comparison
system.
> When the output power detected by the detector if the detector voltage
> exceeds a reference voltage, ALC is developed.
>
> When the rig is at rest, or on receive, the ALC voltage is at zero. The
TX
> system is at full gain. It takes several RF cycles before the ALC voltage
> can climb and limit drive.
>

Hmmm... Is this true even when not driving the linear? When I adjust the
power output
of the transceiver via the front panel control, am I adjusting the ALC
somehow? I didn't
think this was the case.

> I'm not surprised by this. Does Kenwood warn you to overcouple the PA
> slightly before advancing drive? If not, they should. This problem is
> compounded by the fact the 940 certainly has power "overshoot". The load
> control should always be operated beyond the setting where maximum output
> occurs, and you should never depend ALC to keep the power reduced. The
> ALC/ power control system is just too slow.

Appears that Kenwood does not recommend overcoupling the PA before
advancing
the drive. The only recommendation for the load setting when initially
tuning is
to put the load control at 12:00 and start there.

> You are using the 922 at the worst possible condition for arc prevention
> when you run low power at high anode voltage.

Hmmm...but an arc never (or at least never that I can recall) under these
conditions on
my rig at least. Wonder what is going on here...

>
> Yes, but you need a storage scope or a very good very fast peak reading
> meter. Even a Bird 43P is on the slow side for this. There is no doubt
you
> have the problem, because I've yet to see a modern rig that doesn't.
>

> Do you have a fast peak reading meter, or a storage scope? If you don't
> have a fast peak reading meter, how do you know you are driving the 922
> correctly at the power you loaded it up at?

I have an LED peak display on my Tucker antenna tuner, but I don't have
a quantitative idea how fast it is - no storage scope and the Bird I have
is
a slow one. Tried looking with the LED display with fast LC (it is
adjustable to track
slower if desired) - no evidence of peaking, but I'm not confident that it
would see a real fast one.

>
> >Or would it only be there when going into an amp?
>

> the rig. Let's say that level is 200 watts.
>
> Tune the PA with 50 watts, and you are spiking the PA with four times the
> loaded power once in a while on leading edges. Tune the PA up at 120
watts
> drive, and the sipe is still 200 watss but now the PA is loaded with a
> much lower Q and less tank voltage overshoot.

Boy this sounds like a serious design flaw to me, if it is really
happening. Also,
sounds like a lot more final transistors would blow if this were as
widespread as you
seem to believe it is. I wonder why there aren't more dead finals around?

> Aside from that, I'd buy a good peak reading meter (if you don't have
one)
> and OVERLOAD (the loading capacitor set slightly beyond maximum output)
> the PA when tuning before ever appling full power or voltage.
>
> The worse thjing I can think of for both splatter and arcing is to set
the
> loading cap too light, and to throttle back the 940 without using
external
> bias on the ALC.

Ok, just so I'm absolutely clear on what you are recommending, by setting
the loading cap "too light" I understand that to be at large capacitance
values (smaller
numbers on the front) - heavy load settings are lower cap values (bigger
numbers).
Am I interpreting this right?

> Doe this make sense, or do I need to explain some areas better?

I think you are doing well, considering my lack of understanding of some
of these
issues. Thanks for the time and explanations!

Late in replying? I have been trying to find out whether or not the AL-1500 amp. uses a VHF parasitic-oscillation suppressor for what seems like at least a week.
A friend of mine also had a massive disc crash. He was using Windows-95. Are you using Windows-95, David?

> Thank you for your thoughts and suggestions on this matter and I will

Ur welcome, David. Your retrofit kit will go out in the next mail pickup.
Oh yes, and Aunt Minnie told me to say to say hi. ..... Hi-hi.

Please do not smooth up the arc-marks on the plates of the 922's tune-capacitor when you install the retrofit kit.. However, before you remove the 922s factory-stock silver-plated strap, parasitic suppressors please use a dipmeter to check the VHF anode resonance. The best place to make this measurement is at the rear of the HV DC blocking capacitor on the #12 gauge copper buswire that connects the blocking capacitor to the top of the HV-RFC. There are two areas of interest: What is the resonant frequency?, and would you describe the VHF dip as sharp or broad?
These measurements should be repeated after the retrofit kit is installed.

It might be better to switch this discussion to the "Good source of amplifier tips" thread, David. Will, KN6DV, is keeping an archive, so it could be easier for him if the proceedings are in one area.

I am hoping to enlist the knowledge of a few of the amplifier gurus out here with a little problem I have
with an Ameritron AL80 (NOT "A" or "B"). Whenever I attempt to load up on 75 or 160 meters, the
bandswitch begins to arc over. The antennas are resonant (Less than 1.5:1 SWR), I have checked
for cold solder joints, etc., and the amp does perform properly on 10-40 meters. I am not an electronics
genius, so have to ask for a little help every now and then....Thanks in advance for any help offered....

I am sure you are correct...a $90 L-meter has its limitations! Trust me-
the plating is chrome..I have been in the plant and seen the process.
BTW Henry has completely changed the solenoids on the 8K...too many were
having the same problem as you experienced. Talk to Paul Johnson for
details. Also, the high L in the suppressor may counteract the high
output C of the tube..the 8K uses no C1 in the pi-l on 10m because of
this.

Phil, K5PC (what a nice suffix) rightly pointed to my mistake in using a word "dumping" for an ordinary resistor instead of discussing price reductions :-) I even spell-checked that posting but I needed more sophisticated semantics test. On the other hand, English is NOT my mother tongue and I begun lerning it late at the age of 20...
ALC overshoots are real shame with modern radios equiped with a lot of micro-processors. They should be cured at the source and NOT late in the chain... However, tubes can survive them, poor MOSFET's don't...

It seems not to be the case in the TS-940 or in any other transceiver I am familiar with, David. ALC overshoot lasts only about one or two milliseconds, and fully recovers between spoken words. Thus, overshoot spikes continue to occur at the beginning of each new word that is spoken into the microphone. I have seen no evidence of climbing----except in Federal and State taxes.

Amen to that Tom. When I said that ALC-systems in transceivers had a problem with attack-overshoot in "The Nearly Perfect Ampilifier" (QST, 1/94), I was criticized for it by Fred Telewski, WA7TZY, in the 9/94 QST. Telewski said "Measures' comments about ALC being generically flawed are inappropiate." // Any comments, Mr. Telewski?
However, I have not measured the amount of overshoot you claim. The highest overshoot I have measured from a Kenwood radio with my Hewlett Packard oscilloscope was 45% in terms of power, or 20% in terms of RF

peak-voltage. However, a JRD transceiver exhibited a 26% RF peak-voltage overshoot. Even if a transceiver was capable of delivering an overshoot of 300w, the two 3-500Zs would saturate at about 150w drive and the extra drive would not significantly change the peak voltage across the 922's tune-capacitor.

> Appears that Kenwood does not recommend overcoupling the PA before
> advancing
> the drive. ......snip........

Good advice, Tom.

Prior to 1986, I used to wonder too, David. Eimac's Mr. Foote seemingly sent me off in the right direction. Hmmmm. I am still wondering why Eimac's Reid Brandon, W6MTF, told QST's Paul Pagel that Mr. Foote was NOT AUTHORIZED to release such information to Mr. Measures? // Any comments, Reid?

My triggered-sweep oscilloscope works fine---providing one sets the trigger level high enough to begin the sweep only at abnormally high RF peak output voltages. With a storage scope, you would have to use the same trigger setup procedure---however, with a storage 'scope the image lasts all day instead of a second or two.

QST, QST, QST, de AG6K.....is there anyone out there who knows whether or not Tom Rauch's AL-1500 amplifier design usea a VHF parasitic oscillation suppressor?

HELP! I need a power transformer for an old Heathkit GR-2000 television (yeah, I know, it ain't a ham radio, but nobody knows parts scroungin' better than us hams).

The one I need is part # 54-835 and it is the larger of the two power transformers in the set. Buy a replacement off the shelf, you say? The secondary windings are: 59 VAC center tapped, 200 VAC with a tap at 75 volts and 1.3 VAC!!!!! Did Heath have a brother-in-law in the transformer business or what?

Thanks for any help (email me direct--doubt whether this has any universal interest to the ham comunity).

73,

Phil Jockell - N4GWV - philj@ecc-uky.campus.mci.net

If the amplifier in question was a Collins 208-U10, at the 8171/4CX10,000D's anode resonance of around 60MHz, the "short" probably exhibits at least 40 ohms of reactance.

Nice going, Henry, but not fast going by any means, Phil. For years after the article about intermittent VHF parasitic oscillations was published in the October 1988 issue of QST, Henry used silver-plating on its VHF parasitic suppressors. I have been using a resistorless VHF parasitic oscillation suppressor in my Class AB1 4CX3000A amplifier for 7 years. No resistor is used---just two UNequal lengths of nickle-chromium-iron alloy (a.k.a. stainless-steel) shim-stock which are NOT inductively coupled to each other. At VHF, nickle-chromium alloys have enough intrinsic R to get

the job done. According to my dipmeter, the original silver-plated strap exhibited a sharp dip at 68MHz. However the nickle-chromium replacement exhibits a broader and shallower dip at 68MHz. In my mind, better dampening means a duller dip. Apparently, some people think it does not matter. // Any comments, Tom? Any comments Reid?

IMO, Henry's newer suppressors would provide even better VHF-dampening if Henry provided a second VHF current path in the suppressor device with a different amount of L. Two UNequal L, VHF current current paths creates a stagger-tuning broadbanding effect like that in IF transformers when the secondary and primary windings are tuned to different frequencies. Such a suppressor can be made from entirely from strips of stainless steel shimstock. However, to minimize VHF-Q, the width of the stainless-steel strips should be no wider than is necessary to carry the RF circulating current from the tank at 29MHz. IMO, a VHF parasitic suppressor that does not get hot at 29MHz is not going to be dampening/absorbing very much energy above 30MHz.

I still get phone calls from owners of older Henry amplifiers, that use silver-plated "suppressors" who experience what appears to be VHF parasitic arcing at the bandswitch. Jim Day, W6DF, who works on Henry amplifiers, told me that he repeately explained the apparent, intermittent VHF parasitic arcing problem, and its cure, to the powers that be at Henry Radio. It took Henry at least 5 years to figure out that Jim Day knew what he was talking about. ..... . Nice going, Mr. Day. Nice going, Mr. Handy.

I guess you are not familiar with modern test equipment Rich.

The anode circuit of the AL-80B I just measured has two resonances (other
than the ones normally due to HF tank components). One is adjustable over
a range of 63.34 to 22.63 MHz as the plate tuning cap is adjusted. It
moves down in frequency as the capacitor is meshed.

The second resonance is at 152.10 - 161.36 MHz. It moves UP in frequency
as the capacitor is meshed.

With the suppressor removed this resonance moves up to 192.16 MHz.

What can you develop from this data? I'm especially interested in what you
will tell us about Q or impedance, since I also measured those values. I
want to see how close your ESP is to a HP Impedance Analyzer. Also, what
frequency does the PA oscillate on when the suppressor is removed?

Do you want me to E-mail someone the complete data before you reply, so we
can see how close you come without rectangular impedance coordinates for
your calculations?? I can do this, since I already have the Q, impedance,
frequency of oscillation, and so on.

I'm still wondering what you can predict with a GD meter.

==========
If you want a 20 A DC load capability, you don't want a 10 A
transformer, you want a transformer that will deliver the 20 A!
Watch out for AC rating s and DC load ratings on transformers, because
they are not the same, due to the difference in current waveform.
(Please, no arguments about DC in transformers...it should be obvious
I'm referring to the load current after rectification. The current
seen by the diodes and transformer looks a great deal different than
the load current, in terms of duty cycle and waveshape. This is why
transformers can be rated differently.)

RF Gillette's idea of stacking power supplies is cool method of
recycling cheap supplies. I'd recommend using linear ones and not
switchers, for one. Two, you may not have the same regulation, as you
are tripling (possibly more due to wiring) the output impedance
compared to a single supply, and lastly, use plenty of RF bypassing so
you don't have your output voltage go out of regulation due to RF
getting back into the regulator(s).

No help. The frequency sounds in the ballpark, however, this resonance moves DOWN slightly as the tune capacitor is meshed, not UP.

> With the suppressor removed this resonance moves up to 192.16 MHz.

According to Eimac Chart #4264 for the constant current characteristics for a 3-500Z in grounded-grid configuration, the highest anode current shown is 1.8 amperes. Currents above 1.2 amperes are in saturationville. The smallest tube I am aware of that is capable of 10 peak amperes of anode current in linear amplifier service is the 4CX10,000D/8171. You seem to be transplanting the capabilities.

> Rich, I've heard you say that before. The dact is a 3-500Z can output 5-10
> kW before saturating.

I do not recall saying this, Tom.
From personal experience, I know that a healthy 3-500Z begins to saturate when it driven very much above 400mA (approx. equal to 1.2 peak amps) of average anode current. Eimac rates the max. avg. anode current at 400mA. 4000v at 420mA is not likely to produce 5kW to 10kW before saturation occurs. IMO, a 3-500Z can produce about 1100W of clean RF with a 4000v anode supply.

It's too late to demote Mr. Foote, Tom. He retired. Mr. Foote was the Chief Specifications Engineer for Varian-Eimac's Power Grid Division. // Why was Foote NOT AUTHORIZED to release such information in Feb. of 1986?. Any comments, Reid?
The phenomenon that Mr. Foote described was subsequently proven to my satisfaction, and proven to QST's satisfaction. In order to see the phenomenon Mr. Foote described, all it takes is a kaput gold-sputtered tube, a fine toothed saw, a vice, and a microscope. // Lon Cottingham,

K5JV, said he is sending me a box of kaput ceramic tubes. If I find one that is gold-sputtered, I could cut it open and ship it to you for your inspection, Tom. However, you will need a 30x to 50x microscope. Interested?

snip..... With a storage scope, you would have to use the same trigger

Within the loop bandwidth of the PLL, the phase noise at the output,
is equal to the reference osc. noise multiplied by the total division
factor, N. The phase noise outside of the Loop bandwidth is that of
the VCO.
Reference: PLL Primer, by Andrzej Przedpelski

ie, you will decrease phase noise within the loop bandwidth of the
PLL.

> 73 Tom

Hello, Tom:
If you believe that you can prove me wrong, then you should not be afraid to take your dipper and measure the dip-freq. at the AL-80's DC blocking capacitor. The anode resonant frequency is highest when the tuning cap. is at minimum C. The anode resonant frequency is slightly lower when the tuning cap. is at maximum C. Knowing both frequencies would be helpful.

How are you coming on the Q problems, Tom? That second Q problem is a bit tricky. Would you prefer to let me post the answers first, or would you prefer that we simultaneously post the answers at 00:00 hours GMT, or what??? We need to start digging into the Q issue that you brought up, Tom.

Tom: Does the AL-1500 amplifier, which you designed, utilize a VHF suppressor?

Did you answer the question that Jesse asked you:

"Tom, are you absolutely sure it's impossible for a unstable amplifier
to start into oscillation intermittently from switching transcients?"
---73, Jesse, W6KKT
This seems like a fair question, Tom. Roughly 95% of the parasitic
oscillations that I hear about occur when transient currents are present in
the anode circuit. .

Phil, try using one out of an old CB radio. They typically have 100
to 200 uA movements, and they work great in QRP and homebrew gear. I
have used them many times (I always keep a bunch in my junk drawer).
Some are even lighted using small 12v grain-of-wheat light bulbs, and
you could use a small switch to enable/disable the light to save your
battery power.

I see old CB rigs for sale at flea markets for a buck or two apiece
all the time. Doesn't matter if the rig works or not. I've never yet
found a CB with a bad meter movement (except one that was sunk in salt
water when the boat it was installed on went down).

[Remainder of calculation deleted.]

Don't neglect the poor grid circuit.

An amplifier with a VHF parasitic is operating as a tuned-grid tuned-plate oscillator, with tank circuits on each side composed primarily of the tube capacitances and the wiring inductances. As Tom R. has pointed out earlier, the oscillating amplifier is functioning in a common-cathode, grid driven configuration, even in (for normal operation) grounded grid amps.

The parasitic suppressor in the plate lead works in two ways - the much discussed lowering of the Q of the VHF plate circuit resonance AND moving that resonance far in frequency from the grid resonance. The assumption is that the grid resonance is at a higher frequency than the plate to start with, in which case moving the plate resonance lower (suppressor coil), or the grid resonance higher will help. I believe Tom R. mentioned the importance of short direct grounding or bypassing of the grid somewhere back in one of these amplifier threads.

In trying to make sense of all of these discussions, I find it helps to keep the whole circuit in mind. We've got an amplifier with a VHF frequency response that is determined by its input and output circuits, and some feedback through the tube's internal capacitances. If, at any frequency, the gain around the loop (amplifier + feedback path) exceeds unity, the amplifier will oscillate. Anything that sufficiently reduces the maximum gain or feedback will make the amplifier unconditionally stable.

I have an old textbook (Radio Engineers' Handbook, Frederick Terman, 1943) that talks about suppressing VHF parasitics in HF RF amplifiers by several methods -

- A coil alone in the plate lead, to further separate the grid and plate
VHF resonances. No resistor.

- A resistor alone in the plate lead, to dampen the resonance. No added inductance.
This resistor is directly in the VHF tank, but not in the HF tank. The same is true of the resistance component of Rich M.'s suppressors.

- A neutralization circuit that is effective at VHF (reduce the feedback).

Evidently the modern suppressor circuit either wasn't yet developed or wasn't well known when the book was written. But the basic problem was the same, and was well understood.

Hi Dave,

You can achieve the desired current by paralleling two or more secondaries
of the same voltage and current rating. For example two 24V 6A xformers
will yeild 24V at 12A. The only thing you have t watch is that all of
the units are in phase. If two transformers are used and they are out
of phase they will cancel out to 0V. With more than two units the
possibilities are more diverse but easy enough to figure out.

One day I just switched the audio filter on and no sound came
out. When I switch it off, it patches the audio through to
the speaker just fine, but with it turned on, no sound comes
through at all, regardless of the setting of the frequency knob,
selectivity switch, or bass filter switch.

Does anyone have any documentation, or a schematic?

Please email.

Hello,

Call Roy Arnette at Siemens Automotive, Newport News (875-7130). He
will probably have a number to get you on the way to finding what you
need. We purchase a lot of industrial controls from Siemens (of course)
and I'm sure that those folks can point you to the exact place you need.
Also check the Siemens homepage on the internet.

Sorry, but I'm still in the dark, Tom. What is 'psychic'?

> Please explain what we would know (with a grid dip meter measurement)
> other than the reactance crosses zero at that point.
>
I need to find the resonant frequency of a circuit in the mid VHF-range,
whose resonating C is 5pF, but to find it without physicallyconnecting a
measurement device to the circuit under test. A dipmeter can do it.
Dipmeters are also useful for comparing the Q of two circuits that resonate
at the same frequency.

Mil Spec silver plated stranded 22 & 24 AWG high temperature hook up
wire.
50' rolls
5 roll color assortment (250' total) shipped priority 2 day mail $23.
No color choices at this price, just 5 different colors.

great for building your own satellite, amplifier, rewiring the space
shuttle, your own plane, or whatever.

will not melt when you solder it.
rated at 200 degrees C and 600v.

Compare at triple the price. you won't find it cheaper.
If you find it cheaper I would like to know about it.

If interested contact jskalski@acsu.buffalo.edu

Jim (N2GO)

I am interested in trades for amateur equipment for larger quantities.
I have 1000' rolls for $80 shipped CONUS.

> The anti-gun control groups have a snappy slogan that basically says,
"guns don't cause crime any more than flys cause garbage". Without
debating the validity of that particular statement, I think that it's
unfair to blame lawyers for the state of our society. I'm not suggesting
that I agree with the strange things that go on in the "legal system"
(anyone collecting oxymorons??).
On the positive side of this topic, you might note that the Feds have now
decreed that aircraft manufacturers will only be liable for 18 years
after their product has been sold instead of eternity. Common sense does
prevail eventually.
Another point to consider is that many of these unbelievable judgements
have been rendered by juries!! Has the point been reached where we can
no longer trust the juries??
Our society has serious problems and sleazy lawyers are a symptom, not
the problem itself.
Honest, hardworking lawyers do exist and are a valuable commodity when
someone decides to rain on your parade. And yes, they're not
necessarily cheap, but most will try to keep costs down when they know
you're not well-off.

It seems to me that I made it at AG6K mailing list as I received two direct notes from him!

>I was not aware that an L/R VHF parasitic suppressor can be tuned. How is
>this accomplished?

While attempting to reason suppressor calculation, I had difficulties trying to decide the very starting point for the whole process. This variable is desired VHF frequency we wish to suppress and the only other changing factor is plate tuning capacitor. Tube output capacitance is a known fixed value so by selecting proper inductance we achieve parallel resonance at VHF and then damp the circuit by suitable low resistor.

>snip.......
Grow up, Hollywood!

>......see "Calculating Power Dissipation in Parasitic-Suppressor Resistors"
>on page 35 in the March, 1989 *QST*

Any formulas involved? Bring them up after 17 years for evaluation...

W8JI, Tom showed some interesting measured data on the anode circuit.

>The anode circuit of the AL-80B I just measured has two resonances (other
>than the ones normally due to HF tank components). One is adjustable over
>a range of 63.34 to 22.63 MHz as the plate tuning cap is adjusted. It
>moves down in frequency as the capacitor is meshed.

>The second resonance is at 152.10 - 161.36 MHz. It moves UP in frequency
>as the capacitor is meshed.

>With the suppressor removed this resonance moves up to 192.16 MHz.

Second resonance beats laws of physics but there are lot of unwanted side-efects with real components.

The first one would require capacitance change in the order of 7.8 which is impossible in series combination of tube output capacitance and plate tuning variable capacitor.

It is frightening to think that 24 & 28 MHz bands are within plate resonace with closed capacitor! What a quick way to blow suppressors!?

73 de Mario, S56A, N1YU.

P.S. In "S5 3/6/9 A" note I claimed we do NOT need suppressors unless we detect VHF oscilations in finished QRO ("Collins" way). Any comment?

P.S. II Andy, WB6MPT comment is highly appreciated emphasising known phenomena of loss of human knowledge within a short time span. I expierenced that clearly with PC which did all the previous mistakes minicomputers made!

No doubt about it, the best book on analog solid state design is
"Solid state Design for the Radio Amateur", Published by the A.R.R.L.
This book can teach the beginner (assuming he/she knows solid state
fundamentals) everything needed to be able to produce some prettty
high performance receivers and transmitters. Also, looking through
the last 10 to 15 year's worth of QST at your local library will turn
up a goldmine of information on esactly what you are looking for.
Look for articles by Roy Lewallen, Wes Hayward, Doug DeMaw and Breed
(can't remember his first name now.... Gary I think) in particular.
They are a super great bunch of guys, and produce amazing designs...

> Tom R. mentioned the importance of short direct grounding or bypassing
> of the grid somewhere back in one of these amplifier threads.

Yes he did Andy. However I found little difference in the resonant frequency of the grid circuit in a 3-500Z whether the grid was directly-grounded or grounded through capacitors, as is the case in the SB-220. The inductive reactance of the grid seems to be somewhat cancelled by the capacitive reactance of the grid bypass capacitors. I found that with low values of grid bypass C, the grid resonant frequency could be made slightly higher than if direct-grounding was used. This should come as no surprize. For years, people have been using a series capacitor to raise the resonant frequency of vertical antennas. // The degree of frequency lowering provided by a parasitic suppressor does appear to be substantial because the total L in the anode resonant circuit is far greater than the L of the average parasitic suppressor. In some 3-500Z amplifiers the suppressor moves the anode resonance closer to the grid resonance. Despite this, such amplifiers can be made relatively stable. The TL-922 is one such example. However, stability has its price. The 922's beautiful silver-plated-strap parasitic-suppressor inductors need to be replaced.

> unity, the amplifier will oscillate. Anything that sufficiently reduces
> the maximum gain or feedback will make the amplifier unconditionally
> stable.

Yes indeed. The mechanism that appears to reduce VHF gain is that the series-connected VHF suppressor decreases the VHF shunt/parallel load R on the anode. Here's how it appears to accomplish this: VHF suppressors provide series-R in the anode circuit. Using Yeq=1/Z, we convert the

series-R circuit (Z) to its parallel-R equivalent circuit (Y), (or we could do a vice versa using Zeq=1/Y). Thus, the higher the series-R in the anode circuit, the lower the parallel equivalent R-load on the anode. Less VHF load R on the anode = less VHF gain. As Andy said, if the VHF gain can be made low enough, the amplifier is unlikely to be able to sustain a VHF oscillation. ----- (Note: parallel circuits have susceptance (Y). Series circuits have impedance (Z). For any parallel circuit there is a series equivalent circuit. For any series circuit, there is an parallel equivalent circuit)

> I have an old textbook (Radio Engineers' Handbook, Frederick Terman,

> suppressors.

Actually, a VHF suppressor effects both circuits, especially at 29MHz---but not as much as some folks have asserted. OTOH, 29MHz is fairly close to VHF.

> - A neutralization circuit that is effective at VHF (reduce the
> feedback).

Ah yes, but the fly in the ointment is that neutralization neutralizes the amplifier at the operating frequency---but NOT at the anode circuit's resonance frequency.

But the POWER intercepted is proportional to the area and frequency. Adding more turns makes the voltage (terminal impedance) higher, but does not increase receive power available.

Hi Rich,

We absolutely agree on a few things (like exciter power overshoot) but some things don't make sense.

For example, you suggest someone place a VHF radio near an arcing PA, and listen for VHF RF, and site that as proof a parasitic is taking place. Yet any arc has broad bandwidth, and contains energy from dc to light frequencies. While the arc can be detected at VHF, it can be detected at VLF also. It can also be detected by ear, and by eye! I can hear it the arc on an AM BCB portable radio also.

You seem to feel a grid dip meter can be used to measure impedance or Q. Can you please explain how to do that with a grid dip meter? Can I use a grid dip meter to measure the impedance of a feedline? Will it tell me if a circuit is series resonant, or parallel resonant? Can I use a grid dip meter to measure resistance?

You seem to think the presence of a "grid dip indication" (point where reactance crosses zero) means a PA will oscillate at that frequency. Yet I can think of many examples where the PA would actually be LESS prone to oscillation at a resonant frequency. For example, if I made a series resonant path to ground at a given frequency, the gain could go to zero at that frequency. If that occured from the anode to chassis, why would the PA oscillate on that frequency? If I build a TPTG oscillator and put a series resonant circuit in the anode, it won't oscillate at the series resonant frequency.

Finally, I can make a AL-80B oscillate at VHF by removing the suppressor and increasing the HV. Why doesn't that cause the tuning capacitor to arc, or the bandswitch to fail? Why don't the components you single out fail when this parasitic condition is intentionally created? Why, if you are correct that the feedthrough capacitance has something to do with this oscillation, doesn't the cathode affect the frequency or level of the parasitic oscillation? Why do only the anode and grid connections affect the oscillation?

When a Penta-Labs Chinese 3-500Z was used in the oscillating PA, the glass does not melt. Why not, since you determined that was the cause of glass failure?

When I stopped the oscillation and biased the tube into 400 watts of disipation, the glass failed in less than 15 minutes. Yet a spectrum analyzer showed complete RF silence. Why did the glass melt with no RFoscillation, and NOT melt with an oscillation, if the cause was a parasitic as you claimed?

If you can explain any of this, it would make your theories much more believable.

I too once needed a lawyer, and he came thru for me. I think the problem
is the
bottom half of the class. This lower 50% has contemp for the law, and
they are
who the lawyer joke are for. Basically, it is the Judges who have my
contemp, but
then they are lawyers also. And if you say, "What about the judge in my
case, where
I won", I will just say, at one point, the Judge fell asleep, and I won
in spite of him, mainly because of the strength of my lawyer.

Apart from joining ARRL, that is the first workable suggestion that's
been offered.

Remember, the question came from GERMANY.

Strange as it may seem, QST and other American radio magazines are not
available at corner bookstores outside of the USA, or in local
libraries. If you go into a pharmacy outside of the USA to ask for QST,
they will offer a wide range of products to help with your delusional
state... but sorry, no radio magazines.

You are, to some degree, correct.

The proliferation of lawsuits really isn't the fault of the Trial
Lawyers Association. In a sense, they are merely providing a service
to accomodate a demand for legal services in our country.

It is the desire to "get rich quick" (and sueing someone seems to
be a way of doing that with little to no risk if you can get a
lawyer to take your case on a percentage basis, which most will)
that the American people have today [inherently lazy bastards
they are -- the Japanese were right -- they want to lay around
with the good life, no work, have everything paid for them by
someone else -- basically an extension of the welfare-state
mentality that permeates this country today].

Ah, then I see why Mr. Handy's advice was dropped from later Handbooks.
Just as you are doing, he fails to consider the suppressor as a unit,
and insists on treating its components as if they were operating in
isolation. That's an incorrect approach.

>> That advice is, of course, correct, and is the
>> way *every* parasitic suppressor is made today. Even yours. The resistance
>> needs to be in *parallel* with the reactance, however, not in series with
>> it, for best results.
>>
>This is the position of Mr. Rauch, who insists that insignificant VHF
>current flows through the suppressor L. Gary: Do you believe that
>insignificant VHF current flows through the suppressor L?

No, not at all. I believe that significant current flows through the
suppressor circuit. Some through the resistance, and some through the
reactance. If the two currents are approximately equal, then the

resistance and the reactance must also be approximately equal, and
hence the Q must be approximately *1*. Now where I grew up, *1* is
considered low Q.

You *cannot* treat the inductor and the resistor in isolation. They
are two parts of a *parallel circuit*. You *must* analyze the behavior
of the *circuit* as a unit to see what effects it may have.

>> Indeed, which is why there is a *paralleled* resistor across the inductor,
>> to lower the suppressor's *VHF Q*, or more to the point, to increase the

>the pecuilar double-peak in 40m output during tune-up. Other SB-220 owners
>have reported similar results in both of these areas.

If any of this is true, it is because the Q at *HF* has been lowered
by the lossy coil. It has *nothing* to do with the Q of the suppressor
at VHF. Calling this "low VHF Q" is extremely misleading.

> Of late, I have seen plenty of seemingly-questionable VHF Q theories
>proffered hereabouts. If you have access to a dipmeter, Gary, you may (or
>may not) be interested in comparing the dip between a VHF suppressor L made

>comparison, let me know for which amplifier. I will build a low VHF Q
>suppressor and mail it to you--free. The 55-cent stamp is on me. This
>offer is good whether or not you report your findings on this newsgroup.

Rich, measure one of your *suppressors* with your dipmeter, not just the
coil, the whole damn thing. Now replace the nichrome wire with copper wire
and measure the *suppressor* again. If there is a significant difference
at VHF, I will be more than a little surprised.

Zero is pretty strong. It is very hard to prove a negative. How can you
ever be sure you've tested all *possible* conditions?

>In over 20 years of commercial PA design and 34 years of amateur PA design

Then I guess you're better than the boys from RCA and Harris, because
we've had oscillations in the field that they couldn't duplicate back
at the factory, and they had to send field engineers out to find and
fix the problems on site.

I don't dispute this at all. However, if you don't know what the
signal *looks* like, you're just guessing when you adjust the
counter trigger. You might not be measuring what you think you
are at all. That's where the scope is invaluable. It allows you
to see what the waveform looks like so that you can intelligently
adjust your counter to measure it.

Hi Mario
In article <23064@s55tcp.ampr.org>, s56a@s55tcp.ampr.ORG (Marijan Miletic) writes:

>Second resonance beats laws of physics but there are lot of unwanted side-
>efects with real components.

Not really. Only 500 watt boiling gold 8877 grids and photons beat the laws of physics. This stuff is simple common sense. The capacitor looks slightly inductive at that frequency, and inductance increases as the plates are unmeshed! That does not seem strange to me, the path is slightly longer and we are above series resonance. We can consider Xc to be zero at that frequency, and so only the varying path length remains.

>The first one would require capacitance change in the order of 7.8 which
>is impossible in series combination of tube output capacitance and plate
>tuning variable capacitor.

I was looking INTO the anode lead with the network analyzer, to see exactly what the tube "sees". Keep in mind Mario, the tube is a time varying resistance. The output capacitance of the tube is in shunt with this resistance, not in series. We can not place the tube's output capacitance in series with its' resistance and the tuning capacitor C, it is in SHUNT with the tube's time varying resistance.

If we need to know what the tube sees as a load, we MUST always view the system correctly.

>It is frightening to think that 24 & 28 MHz bands are within plate resonace
>with closed capacitor! What a quick way to blow suppressors!?

Do not get lost in the "Hollywood method" of ignoring impedances and only looking at resonances to reach profound conclusions about a complex system.

The tank appears, to the tube and plate choke, as a few thousand ohms at the operating frequency. Even if the suppressor IS series resonant, the power across the suppressor is related to the time integrated value of current pulled from the tank by the tube. The only bands where this is an appreciable factor is on 10 and 15 meters, where the tube output capacitance is part of the tank and larger circulating currents flow through the suppressor throughout the entire RF cycle. If we can make the suppressor survive the resonant VAR problem, everything else is simple.

Do not worry about series suppressor resonance because that component is in series with the tube's time varying resistance and tank impedance at the operating frequency. We only need worry about parallel suppressor resonance or circulating currents due to the tube's output C. That is the real heating problem.

This all makes sense (like the anode swing issue) when you look at it close enough.

cancelled
>by the capacitive reactance of the grid bypass capacitors. I found that
>with low values of grid bypass C, the grid resonant frequency could be
made
>slightly higher than if direct-grounding was used.

Rich,

Tell us HOW you measure the grid resonant frequency of the 3-500Z when the grid is directly grounded. What instrumeentation do you use?

Using my computerized Wiltron network analyzer (which I hope is an acceptable instrument) I measure the following frequencies and transmission losses in a cold tube mounted in an AL-80B chassis, with anode and cathode connections terminated in 50 ohm loads.

No bypass and grids grounded directly:
105.94 MHz (-40.12 dB) parallel grid resonance
168.28 MHz (-82.39 dB) series grid resonance
439.48 MHz (-8.18 dB) parallel grid resonance
and from there almost a straight line to 1 GHz.

SB-220-type mica capacitor bypasses with one inch leads:
129.81 MHz (-32.30 dB) parallel resonance
161.62 MHz (-58.74 dB) series resonance
215.01 MHz (-13.17 dB) parallel resonance
385.46 MHz (-8.24 dB) parallel resonance
575.32 MHz (-30.35 dB) series resonance
611.43 MHz to 1 Ghz an upwardly tilted line to -3.05 dB.

That looks like a major change to me Rich. Both the resonant frequency and transmission loss changes, and it moves in undesirable directions. IN NO CASE does the grid isolation become better!

Perhaps that is also why, in the SB-220, inductance can safely be removed from the parasitic suppressor when the grids are directly grounded through short leads.

Why do you say it has no effect? Can you explain your method?

IC-x7A series radios do not use tone on simplex, however, you can "trick" the radio by setting it to duplex and changing the offset to 0.00, then you can set the tone encoder on.

Hope this helps,

Bruce

Hello all, Thanks for your time, I'm interested in building a couple of Different RF Power Amps, I need Construction Info/Schematics for An amplifier using 1 or more 6146 tubes operational 6 through 12 meters, I would also like to construct the same using A single 4CX250B, then when I finish these I would like to Build a Multi Tube unit using 4CX250B's or one of its slightly larger brothers. I would be willing to pay for any of the above info. If you have any parts you think may be usable in the above projects let me know! Thanks and 73.

..
: Compare at triple the price. you won't find it cheaper.
: If you find it cheaper I would like to know about it.

Since you asked, and assuming others reading the posting might like to know too...

Locally, Boeing Surplus has this sort of thing for about $.40/100 feet. They aren't guaranteed to have it in stock, but seem to pretty often (as you can imagine from what they build). You have to go pick it up there, but I'd guess there are other places around the country that have similar deals on Teflon insulated wire. (I've gotten some wonderful deals on Teflon-insulated coax from Boeing Surplus...)

Hi All,

We're still looking for a solid state Grid Dip Meter (preferably the
Millen Solid State version). Delivery is to Israel.
Can anyone help?

(PS: When responding, please email directly in addition to posting
here, so that no responses are missed).

Hi,

I'm looking for a converter to extend the range of my PRO-36 scanner
(limited to 512MHz). I've heard such beasts exist.
It could either be a complete product, a kit (should be simple
actually) or just a schematic and article of a proven design. Any
leads to such products or companies would be appreceated.

(PS: When responding, please email directly in addition to posting
here, so that no responses are missed).

Your question and answer posting is a good reminder for all on ANY amp - and the additional point worth
checking-numbers (scales) on front panels vary from brand to brand! Either check the manual or
(preferred method!) look under the hood! With power off of course, visually see if capacitor is fully
closed (max cap) at the high or low scale on the front panel.

Keep asking questions and you'll keep pulling out answers!

Good luck!

>

You can get a pretty good idea of where (frequency wise) the thing might oscillate. Or at least where it might ring.

I thought Rich's purpose for the GDO measurements was quite obvious.

What do YOU usually use a grid dip oscillator for? It's a really great tool for finding resonances. And, as you and I both know, if a circuit is going to break into oscillation, it is liable to do it at (you guessed it!) the frequency of resonance. And, since we are talking about parasitic *oscillations* here (among other things), I'd say that makes Rich's GDO measurements pretty significant.

I would have thought that a "recognized amplifier expert" would have seen this right away......

Subject: BUY A BRAND NEW PLAYSTATION FOR ONLY $5!!!!!!!!!
From: heather8@flash.net (Heather)
Date: Sun, 01 Dec 1996 03:27:20 GMT

GUYS, TRY THIS OUT IT REALLY WORKS, I STARTED IT 2 WEEKS AGO AND HAVE
MADE
OVER $500!!

------------------------------------------------------------------------

----------------------------------------
THIS IS THE FAIREST MOST HONEST WAY I KNOW OF TO SHARE THE WEALTH!!

Hello! Would you like to make thousands of dollars, quickly,
legally, with NO CATCH? Then keep reading.... Please thake a few minutes to
read this article, it will change your life, just like it did mine. It's
true! You can make up to or over $50,000 in just 4-6 weeks, maybe
sooner! I SWEAR I'M NOT LYING TO YOU, AND THIS IS NOT A SCAM! If your
interested, please, keep reading. If your not, Then I apologize for
wasting your time.

Here we go, a little while back, I was browsing these
newsgroups, just like you are now, and came across an article similar to
this that said you could make thousands of dollars within weeks with only
an initial investment of $5! So I thought, "Yeah, right, must be a scam",
but I
was curious, like most of us, so I kept reading. Anyway, it said that you
send $1 to each of the 5 names and addresses stated in the article.
You then place your own name and address in the bottom of the list at #5,
and post the article in at least 200 newsgroups. (THERE ARE THOUSANDS!) No
catch, that was it. So after thinking it over, and talking
to a few people first, I tried it. I figured what have I got to lose except
for 5 stamps and $5, right?

Well GUESS WHAT!... within 7 days, I started getting money in
the mail! I was shocked! I still figured it would end soon, and didn't
give it
another thought. But the money just kept coming in. In my first week, I
made about 20 to 30 dollars. By the end of the second week I had a mad
total of over $1,000!!!! In the third week I had over $10,000 and it's
still growing. This is now my fourth week and I have made a total of just
over $42,000 and it's STILL coming in..... It's certainly worth $5, I
```

spent more than that on the lottery!

Let me tell you how this works and most importantly, WHY it
works... also, make sure you print a copy of this article NOW, so you can
get the information off of it as you need it. The process is very simple
and
consists 3 EASY steps:

STEP 1: Get 5 separate pieces of paper and write the following on each
piece of paper:

"PLEASE PUT ME ON YOUR MAILING LIST. YOU ARE NUMBER 4."

Now get five $1 bills and place ONE inside EACH of the 5 pieces of paper
so the bill will not be seen through the envelope tp prevent thievery.
Next, place one paper in each of the 5 envelopes and seal them. You
should now have 5 sealed envelopes, each with a piece of paper stating
the above phrase and a $1 bill. What you are doing is creating a service
by this. THIS IS PERFECTLY LEGAL!

NOW, Mail the 5 envelopes to the following addresses:

1: Ash, 1325 15th street apt #108, Sacramento, CA. 95874

2: A. Wensel, 1306 Park Ave., Williamsport, PA. 17701

3: Hafer's, 952 Anderson Lane., Kalispell, MT. 59901

4:D.Morand 95 Boutelle St.,Leominster,MA 01453-6303

5: M.Mabina, 22 Anderson Street, FT Stewart,GA 31315

STEP 2: Now take the #1 name off of the list that you see above, move the
other 4 names up. (5 becomes 4, 4 becomes 3, etc..) and add YOUR NAME as
number 5 on the list.

STEP 3: Change anything you need to, but try to keep this article as
close to original as possible. Now, Post your ammended article to
at least 200 newsgroups. (I think there is close to 18,000 groups) All
you NEED is 200, but remember, the MORE you post, The more money you
make! Dont know HOW to post in the newsgroups? Well do EXACTLY the
following:

FOR NETSCAPE USERS,

1) Click on any newsgroup, like normal. Then click on 'To News',
which is in the top left corner of the newsgroups page. This will
bring up a message box.

2) Fill in the Subject with a FLASY title, like the one I used.

3) Now, go to the message part of the box and retype this
letter exactly as it is here, with the exception of your few changes.
(remember to add your name to number 5 and move the rest up)

4) When your done typing in the WHOLE letter, click on 'File'
above the send button. Then, 'Save As..' DO NOT SEND YOUR ARTICLE UNTIL YOU
SAVE IT. (so you don't have to type this 200 times :)

5) Now that you have saved the letter, go ahead and send your
first copy! (click that send button in the top left corner)

********6) THIS IS WHERE YOU POST ALL 200! OK, go to ANY newsgroup article
and click the 'To News' button again. Type in your flasy
subject in the SUBJECT BOX, then go to the body part of the message and
leace your cursor here. NOW click on 'Attachment' which is right below the
SUBJECT BOX. click on attach file then find you letter wherever you
saved it. click once on your file and then click 'open' then click
'OK'.
IF you did this right, you should see your filename in the attachment
box and it will be shaded green. NOW POST AWAY!!

IF YOUR USING INTERNET EXPLORER:

It's just as easy, Holding down the left mouse button, highlight
this entire article, then press the 'CTRL' key and 'C' Key at the same time
to
copy this article. Then print the article for your records to have the
names of those you will be sending $1 to. NEXT go to the newsgroups and
press 'POST AN ARTICLE' Type in your fancy subject and click the large
window below. Press 'CTRL' and 'V' and the article will appear in the
message window.

BE SURE TO MAKE YOUR ADDRESS CHANGES TO THE 5 NAMES
Now re-highlight the article and re-copy it so you have the changes... then
all you have to do for each newsgroup is 'CTRL' and 'V'. and press 'POST'
IT's That EASY!

7) THAT'S IT! all you have to do is jump to different newsgroups
and post away, after you get the hang of it, it take about 30 seconds for
each newsgroup! **REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY
YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200**

That's it! You will begin recieving money from around the world
within days! You may eventually want to rent a PO BOX due to the large
amount of mail you recieve. If you wish to stay anonymous, you can invent a
name to use, as long as the postman will deliver it. **JUST MAKE SURE
ALL THE ADDRESSES ARE CORRECT**

Now the WHY part: Out of 200 postings, say I recieve only 5
replies (a very low example) So then I made $5 with my name at #5 on the
letter. Now, each of the 5 persons who just sent me $1 make the MINIMUM
200 postings, each with my name at #4 and only 5 persons respond to each
of the original 5, that is another $25 for me, now those 25 each make 200
MINIMUM posts with my name at #3 and only recieve 5 replies each, I
will bring in an additional $125! NOW, those 125 persons turn around and
post the MINIMUM 200 with my name at #2 and only recieve 5 replies each, I
will Make an additional $625 dollars! OK, NOW here is the FUN part,
EACH of those 625 persons post a MINIMUM 200 letters with my name at #1 and

they each ONLY recieve 5 replies, that just made me $3,125!!! With a original investment of only $5 dollars!

AMAZING! And as I said 5 responses is actually VERY LOW! The average is probably 20 to 30! So lets put those figures at just 15 responses per person. Here is what you will make!

at #5 $15
at #4 $225
at #3 $3,375
at #2 $50,625
at #1 $759,375

When your name is no longer on the list, you just take the latest posting that is appearing in the newgroups, and SEND OUT ANOTHER $5 TO THE NAMES ON THE LIST, PUTTING YOUR NAME AT NUMBER 5 AGAIN. And start posting again. The thing to remember is, do you realize that THOUSANDS OF PEOPLE ALL OVER THE WORLD ARE DOING THE INTERNET AND READING THESE ARTICLES EVERYDAY, JUST LIKE YOU ARE RIGHT NOW!!!

So can you afford $5 dollars and see if it really works? I think so..... People have said, "what if the plan is played out and no one sends you the money? So what! What are the chances of that happening when there are TONS OF NEW HONEST USERS AND NEW HONEST PEOPLE who are joining the Internet and newsgroups everyday and are willing to give it a try? Estimates are at 20,000 to 50,000 new users, every day, with THOUSANDS of those joining the actual Internet. Remember, play FAIRLY and HONESTLY and this WILL WORK, I PROMISE YOU!!! You just have to be honest. Make sure you print this article out RIGHT NOW, also. Try to keep a list of everyone that sends you money and always keep an eye on the newgroups to make sure everyone is playing fairly. REMEMBER, HONESTY IS THE BEST POLICY. YOU DON'T NEED TO CHEAT THE BASIC IDEA TO MAKE THE MONEY!!

GOOD LUCK TO ALL AND PLEASE PLAY FAIRLY AND YOU WILL REAP THE HUGE REWARDS FROM THIS, WHICH IS TONS OF EXTRA CASH. ** By the way, if you try to decieve people by posting the messages with your name in the list and not sending the money to the people already on the list, you will not get as much. Someone I talked to knew someone who did that and he only made about $150 dollars, and that's AFTER seven or eight weeks! Then he sent the 5 $1 bills, people added him to their lists, and in 4-5 weeks, he had over $10K.

THIS IS THE FAIREST AND MOST HONEST WAY I HAVE EVER SEEN TO SHARE THE WEALTH OF THE WORLD WITHOUT COSTING ANYTHING BUT OUR TIME!!!

You also may want to buy mailing and email lists for future $$$. Please remember to declare your extra income. Thanks once again! $$$

The article you are referring to is describing a digital AFC loop, not a PLL. As such,, the error voltage to the VCO is a very slow and sllight change. The VCO will slowly drift within the correction range , but no further.

This approach SHOULD be able to deliver better noise sideband preformance for a given oscillator design than wold be feasible for a PLL, but it is not truly phase locked to a reference.

Obvious good applications would be to retrofit older radios with LC tuned oscillators that are drifty (all of them).

Let's settle this one for once and for all. The Simtel collection is
available all over the place and should be very well know:

"Simtel.Net : List of authorized FTP mirror sites

Simtel.Net, located at Walnut Creek CDROM, is the origin point of
Keith Petersen's world-wide distribution network for Shareware,
Freeware, and Public Domain programs for MS-DOS, Windows 3.x, and
Windows 95. It has more mirror sites than any other archive on the
Internet. Its web pages are also mirrored on many servers around the
world.

FTP.Simtel.Net is the name of the primary distribution site for these
collections. It is actually several ftp sites arranged in a rotating
pattern of IP addresses to help balance the load and to avoid access
problems due to network outages and simultaneous user limits. At the
present time ftp.ou.edu and oak.oakland.edu are the primary sites. Our
files are located in the /pub/simtelnet directory tree on these hosts.

The following sites are authorized mirrors of Simtel.Net as of the
revision date at the end of this document. This list will be
frequently updated as new sites are added.

>fix the problems on site.

I have no control over other's test methods, so I can't speak for or against any of your claims.

It is a fact that any oscillation occuring in the field can be duplicated in the lab, unless the source of oscillation is RF ingress into a low level stage that is not part of the lab tested system.

HI, Tom-------Here is the way I try to operate in a debate: When I read a reply, at the first statement I come to that does not appear to wash, I stop reading, and I deal with it. If time and space permit, I continue reading until I come to another item that does not appear to wash, and I deal with that. I know that if I do not do this, the debate can become diffused and turn into a quagmire.

> No, that's incorrect. The lower anode resonant frequency follows the
> capacitor in the normal manner, but the higher resonant frequency varies
> exactly as I posted.

Exactly? Incorrect? I take "meshed" to mean that the tune cap. is at maximum C. Since the tune C is effectively in series (through the chassis connection) with the anode's C of 5pF, the net C of the two caps. should be maximum when the tune C is at maximum. The net C should be at minimum when the tune C is at minimum, or unmeshed. Since the net C is parallel-resonant with the anode circuit's total L. (see <http://www.vcnet.com/measures/D.a.13.GIF>), therefore, Mr. Rauch's statement (that the resonance moves up in frequency when the tune capacitor is meshed) sounds backwards.......
I will proceed using Tom's figure of 161MHz in the calculation. // The problem is: how does the (161MHz) current divide in a paralleled 85nH Ls and a 100ohm Rs in the AL-80B?......... Using XL=2*Pi*f*L ohms, the reactance of the 85nH Ls = 86 ohms. Applying 1Vrms to the paralleled Rs and Ls, the current throuh Rs is 1 volt divided by 100 ohms=10mA, and the current through the Ls is 1 volt divided by 86 ohms=11.6mA.

Tom Rauch said: "The coil's reactance increases with frequency, and at VHF most of the signal path is through the resistor. It is plainly evident that the dominant component at VHF is the resistor, not the coil."

Tom: do you presently stand by this statement?

Tom: are you prepared to discuss Q?

Hi Jack,

Couldn't you simply go to Radio Shack and get one of their TVI filters? They have 2 or 3 that could either work as-is or be easily modified. (and cheap)

I think what you're looking at is RF (channel 3 or 4), for which
you'll need some sort of demodulator probe to view the video
modulation.

Nah, not really, Tom. I have never seen 300+ watt overshoots.

> For example, you suggest someone place a VHF radio near an arcing PA, and
> listen for VHF RF, and site that as proof a parasitic is taking place.

This was an actual case. Someone phoned me and asked why a nearby VHF field strength meter---about 4 feet away---pegged out whenever he heard/saw the tune cap. in his amplifier arc? (the perf. cover to the final compartment was removed so he could observe the arc)

snip.......
> You seem to feel a grid dip meter can be used to measure impedance or Q.

> grid dip meter to measure the impedance of a feedline? Will it tell me if
> a circuit is series resonant, or parallel resonant? Can I use a grid dip
> meter to measure resistance?

IMO, a dipmeter can NOT be used to measure impedance or absolute Q'.

A dipmeter is basicly used to measure the frequencies of resonances. Also, relative Q can be discerned by comparing the dips of two circuits that resonate on the same frequency. Higher Q is indicated by a sharper dip. Less Q is indicated by a broader dip. (positioning the dipmeter the same distance from either resonant circuit is essential). // IMO, a dipmeter can not be used to find the resonance of a series-resonant circuit unless a conductive path exists between the ends of the seriesed L and C. If such a conduction path does not exist, no current can flow in the series-circuit, and resonace can not be found.. However, a series-resonant circuit whose ends are connected together through a conductor is a parallel-resonant circuit.

> You seem to think the presence of a "grid dip indication" (point where
> reactance crosses zero) means a PA will oscillate at that frequency.

Is this something you think you saw in one of my QST articles, or in e-mail, or from an impression you got during our telephone conversation?

snip......

> Finally, I can make a AL-80B oscillate at VHF by removing the suppressor
> and increasing the HV. Why doesn't that cause the tuning capacitor to arc,
> or the bandswitch to fail? ...snip...

Fortunately, we are about to get into that, Tom. Bob Scott, KF9YH presently has an AL80 whose bandswitch contacts are arcing. I e-mailed Bob, so he just might be showing up on this thread. // More good news: I should be receiving a photocopy of the schematic diagram for the AL1500 8877-ampliier.via snailmail. This will answer the question I have about whether or not the AL1500 uses a VHF parasitic-oscillation suppressor.

Chinese tubes have been improved since they first came on the market, although I have no specifics on the glass-recipe they are currently using. The tubes that Mr. Raich had the melted glass problem with were manufactured around1990.

> When I stopped the oscillation and biased the tube into 400 watts of

How long did the vhf oscillation last?
What was the frequency of oscillation, approximately?
What is the code-date on the tube that you forced to oscillate?

Easytrax is a freeware PCBoard layout program that can
be made to do some drawing. You can export plotter files.

A shareware program called DraftChoice is available. It does not
however print nice looking text.

The best I have found for doing panels like I mention below is
Harvard Graphics 3.0 for DOS. Superb print quality.
You can export plotter files.

Use transparencies. Reverse the image so that it appears to
read backwards. Print it in color if possible and let dry.
Spray with 3M artists spray mount glue on the printed side.
Stick it to your panel. The print is on the inside and
can not be rubbed off. HP Premium transparencies work
better than others. This is also how I make PCBoard negatives minus the
glue of course..

Microsoft Office has all you need to get the job done also.
So does CorelDraw.

One bit of info about printing on transparencies is that Windows
allows you to use a black cartridge with transparencies using a Deskjet.
Thats something I can't do with HG3.

There are some inline filters used by CATV companies which are broad
bandstop filters between 108 and 170MHz. I think they were used to
block midband cable channels from subscribers homes unless they paid
and additional expanded service fee. I'd be interested in one myself.
Since I no longer work for a CATV equipment manufacturer, I don't
get the CATV hardware catalogs like I used to. If anyone knows of
a source for these filters, I'd like to know about it.

I just checked the resonances in my unstock SB-220 which uses 1000pF caps.
to ground the grids. Directly-grounding the Amperex 3-400Z grids increased
the grid-resonant frequency from 72MHz to 77MHz. However, when I

originally tried direct-grounding, the occasional bouts of tune capacitor arcing continued. This result was not surprising since dirctly-grounding the grids moved the grid resonance slightly closer the anode circuit's VHF-resonance.

IMO, there is really no such thing as a 'direct-ground' at RF frequencies. Even 6-inch wide copper ribbon has a finite amount of inductance per unit length. At 100MHz, roughly 30 inches of such material looks like a high-Z RFC.at the open end.

In article <32A50DB7.4EA9@TECLink.net>, "Tom C. Brown, Jr."
<tbrown@TECLink.net> writes:
>
>[Partial]
>> I'm still wondering what you can predict with a GD meter.
>>
>
>You can get a pretty good idea of where (frequency wise) the thing might
>oscillate. Or at least where it might ring.

I guess the correctness of your statement depends heavily on what we consider "a pretty good idea". The GDO is certainly better than looking at the system with a conventional ohm meter, or a battery and a light bulb, but it doesn't indicate anything definitive about ringing or oscillation.

The GDO may dip at a frequency where the PA has the lowest anode impedance (the least gain) or the highest impedance (the most gain). Does your grid dip meter measure impedance? Does it have a scale that indicates Q, R, or X ? If not, it tells you almost nothing of major importance in a complex system.

>I thought Rich's purpose for the GDO measurements was quite obvious.

Not to me. It's no more obvious than how a 25 watt rated grid can dissipate 500 watts. Does anyone want to call Mr. Miklos about this or the other claims like photons??

>What do YOU usually use a grid dip oscillator for?

I don't. I did in the 60's when I was building transmitters and receivers. The last time I took mine off the shelf was to measure the the resonant frequency of a parallel tuned circuit. In that case, I didn't need to know the Q, R, or X. I just needed to see where it was resonant at. Even a MFJ-259 will tell you much more than a grid meter, so why use a GDO in general applications like this?

>It's a really great
>tool for finding resonances.

Well, kind of. I would agree if you left the word "great" out. Simple would be OK, crude would be better. It is useful if we ONLY need to know the resonant frequency of a simple circuit, like a parallel or series lumped L/C circuit.

>And, as you and I both know, if a circuit
>is going to break into oscillation, it is liable to do it at (you
>guessed it!) the frequency of resonance.

You may know or think that, but I don't. The frequency where a circuit oscillates is often much more complex than that.

Resonance (as measured by a dip meter) merely indicates the point where maximum energy is removed from the dip meter's oscillator tank. It tells us a little bit about resonance in a complex system, but it just as likely may indicate the frequency where oscillation can NOT occur as the one where it does. In something as complex as a PA, it would be pure blind luck if the system oscillated at any particular "dip frequency".

>And, since we are talking
>about parasitic *oscillations* here (among other things), I'd say that
>makes Rich's GDO measurements pretty significant.
>I would have thought that a "recognized amplifier expert" would have
>seen this right away......

Tom, it's bad enough when one person turns this into a personal issue by constantly throwing barbs and personal digs, and making up stories about conversations and letters. I fully expect that from some people, because they view technical disagreement as ego damage or something very personal. That kind of behavior is childish and has no place in a technical discussion. If you see me do it, correct me and I will quit doing it... and I hope you will do the same.

Do you understand how a GDO actually works internally? Do you understand what makes an oscillator oscillate? If you do, why do you think a dip on the meter indicates a problematic oscillation may occur?

Imagine I place this circuit from the anode to ground.

anode-----www---] [----(((((((((-----ground
res cap ind

With R a low value, this circuit will dip at the resonant frequency of the L/C combo. In a TPTG oscillator, would you say the stage is more or less likely to oscillate at that frequency?

What if I have a TPTG oscillator with the grid parallel resonant at 120 MHz and the anode parallel resonant at 190 MHz. Would you say the system is more likely to oscillate near 120 or 190 MHz?

Suppose the VHF anode Q is one or two, do you think adding nichrome to the suppressor inductor will lower the VHF Q substantially? If so, can you explain how?

Regretably a check of the license data base fails to locate this
individual, so I have to presume that he is unlicensed, and seeking
information for an 11 meter amp. Suggest to all to ignore further
requests for information.

I personally think that the best thing we could do was to give congress,
(etc.) 5 years to re-touch all of the laws to make them understandable
by the average product of our school system. It would be their choice as
to modifying the laws or improving the education system! ;o)

If it has been so poorly written that only a lawyer can read it, and two
lawyers come to different opinions of what it means, then it should not
be binding! (Think what that would do the the tax structure).

Source record: 100007

********** PANORAMIC DISPLAY FOR YAESU FT-1000 ***************

Hello all, Just spoke to Jerry Vogt from "Hamtronics, Inc". He said
that if they get 40-50 committed customers they will design a "black
box" that
would connect between the Yaesu FT-1000 and a Kenwood Scope (SM220 w/BS8
or
SM230), for PANORAMIC DISPLAY use!
The FT-1000 comes with the IF OUT jack, and even refers hooking a
bandscope to it in the manual, but they never made one. The Kenwood
scopes work
excellent and are readily available new and used. The IF's (8.83 MHz)
don't
match, however.

A circuit is needed to downconvert the FT-1000's 73.62 MHz I.F. to
Kenwood's 8.83 MHz I.F. HAMTRONICS will provide the necessary mixer
and Xtal controlled oscillator (all in one small shielded box) to do
the work! This IS rather specific, but it will obviously work with
any other 73.62 IF. Not sure what the other Yaesu's or the MP has.

**** Please respond either to me (news, and email), or to Jerry Vogt
at the Hamtronics site: http://www.hamtronics.com/hamxHome.html
Just a brief, "Count me in, I want one!!" type of message will do.
If the count is high enough, we're in! They'll make em' Tell your
friends!!
It's too early to know the price, but their similar converters are
very affordable. Thank you all!! -- Richard Valentine, N1SQJ

A line of video is 63 usec. long so you should set your scope to 10
usec. per
div also set the input to DC, and start with the trigger very negative
and
bring it up until you get a lock (the negative sync pulse is the only
stable
part of the video signal that a scope can lock on to).

> 73, Tom KJ5IE

Plus:

Don't forget that Rich was not making exact, quantified measurements with the GDO. He was (1) finding resonances in the circuit *WITHOUT* attaching anything physically to the circuit and he was (2) able to compare the Q in a "before and after" situation by just looking at the response of the dip meter in each case. In other words, he was able to say that the Q was greater or less after swapping the suppressors. If *you* are unable to make such judgements with a GDO, then I guess you really wouldn't have much use for one.....

In one case, he saw that the Q at one particular VHF resonant point was visibly and substantially less after doing NOTHING but replacing the suppressor.

Now, in THAT particular case, if the act of changing the suppressor did not affect the Q at that VHF frequency, then what did? And do we agree that a change in the Q at a VHF resonant point is indeed important? Or do you believe the Q at the (or one of the) VHF resonant points in unimportant when considering an amp's propensity to oscillate?

Have you ever been present during a catastrophic "parasitic event"? If so, then you should know that such an event is not even close to the same thing as a controlled oscillation in laboratory conditions. Gary's comment about the RCA and Harris field guys is very appropriate here. You're contradicting a lot of high powered folks when you catagorically dismiss the parasitic problem.

Of course, you maintain that "the whole staff" at Eimac agrees with you, but you have only identified *one* person at Eimac so far. Surely we can all agree that one person does not make up "the whole staff".

Oh, and I asked before.....what is Mr. Brandon's official title at Eimac?

Jumping back, for a second.....

Did you make the analysis with your HP network analyzer *without* hooking *anything* physically to the circuit under test? If not, then the data you collected concerning the resonant points is suspect. Anytime you connect something conductive (like a probe) to a circuit and start measuring resonant frequencies up in the range where "stray reactances" can be a significant part of the whole picture, the results may indeed be affected (possibly substantially) by the very connection of the probe. I have seen this before, and believe me, it *is* a concern.

Now, if you *did* make all your measurements with no physical connection to the circuit, and without overcoupling anything in any way to the circuit, then please disregard the above. Just a thought......

73, Tom KJ5IE

A possibility.... Either one of two circuits should fit your requirements, even though they are "over kill". the amp described by the Motorola Co. paper "AR 313" is rated 300 watts out, 10-150 mhz at Vcc of 12 to 28 volts (I expect full pwr rating is for max voltage) from 15 watts drive. The other is the paper titled "AR 305". This amp is similar, except it requires a Vcc of 50 volts. Your 7 watts should give you about 150 out with plenty of "head-room" (they are linear). They use a rather expensive dual FET transistor (MFR141G or MRF151G, respectively). These amps should have a filter placed in the output. This is not part of the circuit described.

There is a company in the US that sells all the parts to build one... is: Communications Concepts, Inc.

Another possibility: Can you obtain an old low-band FM (~48 Mhz in US) 2-way? Most solid state units will have a seperate PA board which requires (usually) several tens to 100s of mwt drive using several stages and will likely tune your freq. I have had luck in isolating the higher power stages so they can be driven from a high level source without an attenuator. This will work great for FM or CW. If you need linear, some of the PA modules can be modified to apply forward bias, but the output must usually be derated (PEAK AM will need to be lower than the saturated output level). I also suspect the FET amps above will provide much better linearity than biasing-up the PA module.

3614. Seriers IC-x7 Simplex Tone Encoder Operation

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-04 00:00:00 UTC
From: robmitch@vaxxine.com
Message-ID: <32a7f0da.10115088@news.vaxxine.com>
Source record: 100078

Procedure to use Tone Encoder for Simplex Operation for IC-x7 Series
Radios

First set freg. then put either + or - duplex and then
change the offset from 600
in increments of 100 down to 0.00 offset with the offset write button
(Item 8 pages 6 &
7 of the manual) leaving the duplex switch on, then set the tone freq
in the normal way.
As far as the radio is concerned it is on duplex. The difference is
that the duplex
transmit freq. is the same as the receive freq instead of + or - 600.

It works great and thnaks to Bruce Martin for the information.

Don,
I've used a fairly inexpensive Desktop Publishing program to layout things like panels and also to do my own QSL cards! It's called Arts and Letters Express, and the graphics program that goes with it is called Picture Perfect. If you aren't doing any real serious drafting work, there are several shareware drawing programs available. If your stuff is REAL simple, just use the graphics program that comes with windows.

>noise within the loop bandwidth will be mostly canceled by the PLL
>(it can't cancel it all - it doesn't start to react untill it detects
>a change has already occured), but higher freq noise components
>above the loop time constants will not be canceled.

Really, the two main points to improved Phase noise in a PLL system
are:
1. the phase noise of the reference osc.
2. The PLL will greatly improve the VCO's phase noise inside the loop
bandwidth.

The reference osc is the critical part.
Hence, the best Reference osc. is a low phase noise TCXO.

It is always good design practice to have a low phase noise VCO.
But good results are obtained if all other paramaters are optimized as
best as possible, reagrding loop components, divider values, etc.

John,
I am looking for a similar schematic for TR switching at low power HF.
The application is a stand-alone RF sensed TR box for use at QRP using
seperate RX and TX. If you run into something like this, could you
let me know?

RE: Grid Dip Meter

Hi Gary,

In article <1996Dec3.193918.17633@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:
>
>Rich, measure one of your *suppressors* with your dipmeter, not just the >coil, the whole damn thing. Now replace the nichrome wire with copper wire
>and measure the *suppressor* again. If there is a significant difference >at VHF, I will be more than a little surprised.

This was my point in asking Richard what he intended to do with the grid dip meter. It's the single worse "tool" (I certainly wouldn't call it an instrument) for measuring a complex circuit's RF characteristics.

The dip meter doesn't even measure the reactance zero-crossing reliably, it simply measures the suck-out of energy from the dip coil. Perhaps a more correct description is the GDO measures energy absortion via the coefficient of coupling between the dip meter and the circuit.

NONE of this has much to do with the behavior of the circuit at RF, only a person with little comprehension of resonant systems would think it did. A dip does NOT guarantee an oscillation, it very well might do just the OPPOSITE! It will not tell us the Q or any other important parameter.

For example, the dip meter placed next to a resonant system with poor (lossy) mutual coupling can show a shallow narrow dip, but if coupling is increased the dip will get wider and broader. That's why the dip meter's scale is not calibrated in ohms, Q, or rectangular impedance coordinates.

Secondly, the GD meter couples energy into the system (excites the system) differently than the normal operating conditions do. You may have a crude idea something is happening, but you have no idea what the system "looks like" for normal excitation. All you know is the circuit has higher mutual coupling at that frequency to some type of loss at that point in the system. The higher the coupling to the loss, the more pronounced the dip.

My reason for asking what Rich intended to DO with the grid dip meter was to see if he understood what the meter really measures. I wanted to see, if as with the photons and 500 watt 8877 grids, he made another giant unscientific leap of faith in the attempt to support his wild theories.

Gary, you are right on target with the Q issue. The Q of the suppressor Rich outlined was unity. Adding nichrome lowers the VHF Q an insignificant amount. If the suppressor became a perfect zero reactance resistance, the

Q would only drop from one to zero. Big deal.

I'm with you on this one Gary.

I consider a Q of one VERY low Q. The nichrome does reduce HF Q, and that lowers the tendency for tank overshoot when the PA is overdriven or underloaded. It also will help stabilize the PA at HF, but certainly NOT at VHF.

I am very suspect of any person who represents himself as an expert on a technique, and who so clearly fails to understand how to measure things and how to analyze a simple parallel L/R circuit. This "lower VHF Q thing" fits right in the same bin as the photons, 500 watt 8877 grids, VHF arcing tuning caps and switchs, peak tank voltage not being able to exceed the supply voltage, and so on.

Why did this stuff about nichrome apear in the early years? It's easy to understand why.

Back then, tubes had long grid and anode leads. Grounded grid operation was virtually unheard of, everything was grid driven and mostly used high feedback triodes. Shielding was very poor, even metal chassis' were rare in homebrew equipment.

Because of all this, PA's oscillated readily. The problem was uncontrolled feedback below, at, and above the operating frequency. Any resistive wiring helped stability, because the whole PA was laden with uncontrolled and "unfixable" feedback paths. The typical PA had as much a tendency to oscillate at the desired operating frequency as at other frequencies.

Distributed loss at and near the operating frequency is the only universal cure when layout, components, and circuitry are that bad.

Moving such "cures" to a modern PA should be done only with the understanding of what is actually being accomplished. Technology was very different long ago.

I am looking for data on CV1924 and QY4-250 (CV2131) valves. Absolute max ratings and recommended operating paramaters. Is there an online source of this data? The ARRL handbook gives some info on the second valve, but it would be nice to have the factory specs.

I have scored a dozen new QY4-250's and have a 2nd hand amp with 2xCV1924 (parallel) sitting under my desk, and would like to double check the operating values. The gear is needed for the Kiwi Contest team at ZM2K. Checked out Rich Measures home page...excellent stuff.

Forgot your question had never been answered in the flurry with the
"Band Nazi's" I'd check with the Amateur Radio Handbook preferable an
older edition, none of the circuitry is complex on paper, but sometimes
the practice is. Last I saw, there were several amplifiers along the
lines of what you talk about. Might even make good toasters..heh heh.

That is a good analogy, a frequency counter with a d/a converter. I
believe it is the basic idea, though there may be variations. You have a
time base, a gate, and some counters.

In fact, around 1978 or so Rohde had an article in Ham Radio Magazine
about adding this kind of frequency control to a frequency counter.
There was a followup letter in a later issue by someone who did it
in an even simpler fashion.

The simplified version, just the stabilizer, has the advantage that it
is compact and draws less current. On the other hand, making a frequency
counter is not all that costly or difficult at this time, and you have the
advantage of getting a frequency readout along with the stabilization.
What route to take might depend on whether you were trying to upgrade
an old piece of equipment (which might already have a reasonable dial)
or a portable piece of equipment, where you don't care so much about
exact frequency (don't a lot of QRP rigs have simple dial readouts?)
or want the current drain. On the other hand, provided you can fit
the readouts in, the counter will not take all that much more space
and with CMOS can still be low current. You could add a switch to
disable the readouts until needed.

Realizing that I am at great risk of being accused of picking a language nit..

Mario -

From the subject line in this post, I get the impression that the correction offered to you was, perhaps, a greater error than the original mistake.

I surmise that the word you were meaning to use was DAMPING, but that you were advised that it was damPENing. A lot of native speakers of English make this mistake, using dampening when they mean damping.

To dampen is to make wet.
To damp is to cause to die out, to reduce, attenuate, suppress.

So, if one is concerned about ALC overshoots, I would assume one would want to suppress them, not put water on them.

As an undergraduate, I saw an Elec. Engr. professor absolutely skewer a student over this. I've never forgotten it.

As I said, I may be accused of being excessively picky. However, use of the word dampen is mistaken, however widespread it may be.

Shields up.

This is for everyone here that has been looking for
a excellent PC design software package for Windows.

Try the Ivex web site at http://www.ivex.com

We just bought the non-shareware version and it is
only $29.00 from Mouser Electronics but you can
down load a full operational shareware version of the
program from their web site for free. The only catch
is that it will only plot 100 pin points, but for
Ham use that is plenty. The $29.00 version will
plot 220 pins and upgrades can be purchased to go
upwards of 900 pins. The manual is also offered
online, so full documentation is also avaliable,
unlike many other shareware and low buck PCB software
I have tried in the past.

This software is the best I have seen in the under
$1000 price class. It supports Gerber routing and
has many other features that only the kilo-buck software
have.

It is well worth the half of an hour it takes to
download.

Partially correct. And a common misrepresentation of why emphasis is
used in FM systems.

The output of an FM detector has the characteristic curve of a
high-pass filter. That is to say an FM det. has higher noise output
with increasing frequency. - In it's detection bandwidth.
So a "de emphasis" filter is added to it;s output to flatten the noise
response.
This requires a pre-emphasis ckt at the transmitter.
So the main point is that Pre-emphasis is _required_ by the use of
De-emphasis in FM detectors.

When the pre and de are combined, the result is a flat freq. response.

I would like to see info on the effect of modulation index/sideband
energy, due to the pre-emphasis filter.

Rich,

We need to talk more about how PA's work, and how to measure important parameters than all these unrelated Edisonian test methods. But first, I wonder why Vectronics stopped using the Penta Chinese tubes if your suppressors fixed the problem? I also wonder why they stoped using your suppressors if they helped PA life?

In article <measures-ya023180000412960910540001@news.vcnet.com>, measures@mail.vcnet.com (R. L. Measures) writes:

>> For example, you suggest someone place a VHF radio near an arcing PA, and
>> listen for VHF RF, and site that as proof a parasitic is taking place.
>
> This was an actual case. Someone phoned me and asked why a nearby VHF
>field strength meter---about 4 feet away---pegged out whenever he heard/saw
>the tune cap. in his amplifier arc? (the perf. cover to the final
>compartment was removed so he could observe the arc)

All that test indicates is there was VHF energy present, which we all know is present in any arc. For example, my two meter radio's S meter pins and the squelch opens when my HF antenna arcs. The two meter antenna is over 100 feet from my HF antenna. Does that mean my HF antenna has parasitics? Of course not.

If I turn on a wall switch, and hold my two meter handheld near the switch, I hear it click. If I hold the switch almost closed, and make the switch arc, I hear an S-9 plus noise on two meters. Does that mean my wall switch needs nichrome suppressors to cure its arcing?

I hear lightning discharges and corona discharges on my two meter radio. Does that mean lightning has parasitics?

>IMO, a dipmeter can NOT be used to measure impedance or absolute Q'.
>A dipmeter is basicly used to measure the frequencies of resonances.
<snip>
>a series-resonant circuit whose
>ends are connected together through a conductor is a parallel-resonant
>circuit.

At least we agree on this point. The dip meter tells us next to nothing when it is used to measure a complex circuit. We have no idea if it is indicating a series or parallel resonance as viewed by the tube element being "dipped". We have no idea what the Q is, or if the impedance is high or low at the tube element.

>> When a Penta-Labs Chinese 3-500Z was used in the oscillating PA, the glass
>> does not melt. Why not, since you determined that was the cause of glass
>> failure?
>
>Chinese tubes have been improved since they first came on the market,
>although I have no specifics on the glass-recipe they are currently using.
>The tubes that Mr. Raich had the melted glass problem with were
>manufactured around1990.

This was an old tube, one remaining from a batch purchased from Penta several months after they were introduced. Here's what I think you are implying:

1.) If the glass would have melted during the parasitic, it would have been the bad glass problem (like the kind that was never fixed when Vectronics installed your kits).

2.) Since the glass melted and sucked a hole in at less than rated dissipation after a short period of dc operation, it may be different recipe glass.

Rich, it seems like everything NOT supporting your claims is questionable. If it supports your claims it is data worth etching in stone.

The Q of the nichrome suppressor at VHF you gave as an example is only about 1 at 100 MHz. The Q of the regular suppressor at VHF is a tiny bit larger, 1.14. Do you think a Q reduction from 1.14 to a Q of one will cure oscillations that melt glass? Do you think it will cure all oscillations?

Nichrome lowers Q much more on 20 MHz than 200 MHz. Your "low VHF Q" suppressors decrease the likelyhood of arcs and make tuning slightly "smoother" because of the lower HF Q, and not because of any "improvement" at VHF. That much can be proven.

Like Gary said, measure the suppressor with the resistor in place Rich. Otherwise your test is a waste of time. Your suppressor will help some problems, but NOT VHF oscillations.

><http://www.vcnet.com/measures/D.a.13.GIF>), therefore, Mr. Rauch's
>statement (that the resonance moves up in frequency when the tune
capacitor
>is meshed) sounds backwards......

You only think that because you have no idea what the plate tuning
capacitor looks like, impedance wise, at frequencies above 150 MHz. I
expect that, since you do not have access to more elaborate test
equipment.

When the capacitor (as with almost any capacitor) passes its' series
resonate point, it looks inductive. It does not have a high amount of
inductive reactance, but it has some. Above the series resonat frequency,
this inductive reactance increases as the plates are unmeshed. That is
because the shunt capacitance is far down the plate, and is such a low
impedance the series inductance is the dominating reactance.

This is a common effect in RF components. Large vacuum capacitors exhibit
the same effect (but up in the upper UHF range), as they are unmeshed they
become MORE inductive.

HF roller inductors exhibit a "mirror" effect. As inductance is lowered,
the VHF impedance null moves LOWER in frequency. This can be seen on a
network analyzer. That's why some rollers quit working at the upper end of
HF, and start arcing, overheating, or just won't "tune".

Most experienced RF designers are aware of these effects.

> I will proceed using Tom's figure of 161MHz in the calculation. // The
>problem is: how does the (161MHz) current divide in a paralleled 85nH Ls
>and a 100ohm Rs in the AL-80B?

Sorry Rich, wrong frequency. The AL80B I tested did not oscillate there.
It oscillated around 182 Mhz.

..... Using XL=2*Pi*f*L ohms, the
>reactance of the 85nH Ls = 86 ohms. Applying 1Vrms to the paralleled Rs
>and Ls, the current throuh Rs is 1 volt divided by 100 ohms=10mA,
>and the current through the Ls is 1 volt divided by 86 ohms=11.6mA.

That is for an inductior of infinite Q, and neglects stray coupling and capaciatance. The AROUND (remember I plainly indicated ~85 nH) 85 nH inductor, actually measures slightly higher than it calculates or measures in free air when it is installed over the resistor.

This calculation is a wasted exercise when dealing with "standard" components at VHF. The actual characteristics are different than the textbook perfect components, but I will allow the use of perfect components for arguements sake if you at least use the correct frequency.

> Tom Rauch said: "The coil's reactance increases with frequency, and at
>VHF most of the signal path is through the resistor. It is plainly evident
>that the dominant component at VHF is the resistor, not the coil."

To put my statement in the context given, one of describing the merits of your nichrome at VHF, let's calculate the Q (it measures 0.8 on my HP) at 180 MHz. Lets calculate the change in Q when nichrome is added. Tell me what gauge nichrome you use and the length, or mail me some, and I'll calculate or measure the 180 MHz Q.

>Tom: do you presently stand by this statement?

Absolutely. The dominant component controling Q is the resistor, not the ESR of the inductor. Adding nichrome makes little difference in VHF Q. If the parasitic suppressor I tested was replaced with a pure 100 ohms resistance (no distributed inductance or suppressor coil) the q would be zero.

Is a Q change from 0.8 (by actual measurement) to zero a large improvement?? What about if the suppressor Q was one? Is a change from one to zero a large change?

measures@mail.vcnet.com (R. L. Measures) writes:

>
>Rich measures the resonance with a dipmeter, by inductively-coupling the
>dipmeter to a grid pin on the tube socket and searching for the dip..

You have no idea if you are reading grid resonance, or a resonance effect
in the leads near the socket. The only thing that measures the impedance
of the grid to ground (the effective shielding or impedance of the grid)
is passing a signal from the anode to the cathode.

The impedance of the grid is much different than indicated by the view of
a single pin with a crude dip meter.

>> SB-220-type mica capacitor bypasses with one inch leads:
>> 129.81 MHz (-32.30 dB) parallel resonance
>> 161.62 MHz (-58.74 dB) series resonance
>snip...
>>
>> That looks like a major change to me Rich.
>
>I do not see a comparison.

This is typical, I gave both sets of data and you ignore it. Let me repeat
it.

No bypass and grids grounded directly:
105.94 MHz (-40.12 dB) parallel grid resonance
168.28 MHz (-82.39 dB) series grid resonance
439.48 MHz (-8.18 dB) parallel grid resonance
and from there almost a straight line to 1 GHz.

SB-220-type mica capacitor bypasses with one inch leads:
129.81 MHz (-32.30 dB) parallel resonance
161.62 MHz (-58.74 dB) series resonance
215.01 MHz (-13.17 dB) parallel resonance
385.46 MHz (-8.24 dB) parallel resonance
575.32 MHz (-30.35 dB) series resonance
611.43 MHz to 1 Ghz an upwardly tilted line to -3.05 dB.

Both the resonant frequency and transmission loss changes, and it moves in
undesirable directions. IN NO CASE does the grid isolation become better!

Perhaps that is also why, in the SB-220, inductance can safely be removed
from the parasitic suppressor when the grids are directly grounded through
short leads.

>I just checked the resonances in my unstock SB-220 which uses 1000pF
caps.

You have no idea what the anode or grids resonant frequency is with your
GDO. It is the wrong device being used the wrong way.
.
>IMO, there is really no such thing as a 'direct-ground' at RF
frequencies.
>Even 6-inch wide copper ribbon has a finite amount of inductance per
unit
>length. At 100MHz, roughly 30 inches of such material looks like a
high-Z
>RFC.at the open end.

Perhaps you call Z< 100 ohms "high Z". The wider conductor has a lower
surge impedance, and a lower impedance when resonant. A thin conductor
would have high Z, but a six inch wide conductor would look like a low
impedance.

In any event, few designers use 30 inch #14 leads in tank circuits. If
they used a 30 inch six inch wide lead inside a cabinet, the impedance
would be *very* low at VHF.

You gave a very poor example, make the conductor with higher surge Zo and
it will be true.

>/Tom trum@lysator.liu.se
Tom, can't help on the receiver information. However, if you want
wesat pictures, it may be easier to copy the already processed
pictures on the hf bands. You should have good clear copy on signals
from canada and halifax nova scotia. Find these between 3 and 8.5
mhz with good copy in the early evening. You can find good display
software from dl5yec called HAMCOMM. It will display rtty,cw,fax and
sstv on a vga monitor. Many many more sources of software also.
Happy hunting. (I once owned a military wefax receiver that weighed
about 70 pounds. Still have it, but haven't used it in years. Found
that the hf pictures from Canadian Metoc and NOAA were far better!

Actually, most of them include switches that are sufficiently rated to
turn the lamp on and off at full power. Deleting the touch circuitry, and
wiring up the lamp as a regular turn on/turn off lamp works quite well.
If you really want a quiet solution, and a two level lamp, i.e. full
brightness, and almost half, a diode (at least 400 PIV & 6 Amps for
surviving just normal usage) and a dual position switch work quite well.
Since most people don't want less than about half of full brightness, it's
a much better solution than playing with triacs and the like and doesn't
produce lots of RF noise.

I sometimes consider petitioning the FCC to ban such junk from the U.S.
market, because it interferes with working reliable rf gear without need,
but it's now pointless, people want their dimmers, and touch lamps
regardless of what people they consider faceless guv'mint buro crats say
should happen. -art clemons- n8blk/3

Source record: 100030

Hi Jack--

Seems like there are at least a couple of paths you could take, depending upon your application. If you are not transmitting through the filter, you could make up a 2-3 section LC bandpass configuration using Hi-Q caps (much like Tucker does with their intermod filter). This will introduce 5-6 dB loss in the passband, but rejection outside the passband can easily exceed 40 dB. As an alternative, if you are transmitting through the filter, you could make a very high Q "suckout" trap for 152 MHz. If the Q is high enough, loss at 146 MHz will be negligible while attenuation at the pager frequencies might be 20-30 dB. I would avoid inexpensive off-the-shelf filters made with cheap ceramic caps. From my experience (which isn't all that extensive), I've found that to get good results, you'll need low-loss high-Q components.

Clearly, you have no concept of modern network measurement techniques and I'm not about to give you a free lesson. I recently retired after 30 years with a major aerospace firm where I was engaged for most of that time in making r-f and microwave measurements and doing failure analysis on everything from components to all-up missiles.

I can assure you, that we "hooked something" to every damn one of these devices in order to characterize it electrically. Tom has provided data in the form of |S21|, ie, the magnitude of the forward transmission component. In layman's terms, this is the "gain" of the device, expressed in dB, vs. frequency. Viewed graphically, you would (he did) see the peaks and nulls of transmission through the tube.

A series resonant grid will be a low Z impedance to ground and express a minimum "gain" (high loss) through the path from cathode to plate. Conversely, a parallel resonant situation will do the opposite.

I'm not hereby either arguing for or against anybody's opinions on suppresser performance, indeed I'm formulating my own, but I will certainly defend Tom's measurement technique against your criticism

You mean like the way you have avoided questions like (1) Who is Mr. XXX at Eimac? and (2) Who are all those folks at Eimac who agree with you on the parasitics issue?

I know you are sick of hearing those questions asked, Tom, but don't forget, YOU brought both issues up in this thread. I didn't. Rich didn't. We just asked for real information once YOU brought it all up. And as soon as we asked for real, verifiable information, you dropped the subject and have pleaded with us to do the same.

Actually, in my opinion, your (1) inability (or flat refusal) to answer either question, and (2) your intense desire to drop both subjects *IS* an answer to both questions. Quite a revealing answer, I would say.

Oops. It looks like Mr. Rauch's statement that insignificant current flows
in Ls is in deep feces---so here it comes........

> That is for an inductior of infinite Q, and neglects stray coupling and
> capaciatance. The AROUND (remember I plainly indicated ~85 nH) 85 nH
> inductor, actually......snip.....

....snip,,,,,,,,,,,on and on. ....Cough, cough. Bzzzzzzzzzzt At this
rate my smoke detector is going to need a new battery by December.

Mr. Rauch proposed that I calculate the currents for an Ls of 85nH, a
parallel Rs of 100 ohms, at a frequency of 161MHz. I complied. Now it
seems that the apparently correct answers are NOT correct.

>level stage that is not part of the lab tested system.

In *theory* that's correct. But in practice you never test every
possible condition a priori. That's what happened to RCA with the
TT50H. When fed to our 1954 vintage RCA filterplexer, and driven
with a certain page of our Vidifont character generator which had
energy at certain seldom used frequencies in the video passband,
the thing would break into a parasitic oscillation which ate the
screen grid of the 8916. The fix was a paddle in the cavity which
broke up that particular resonance mode.

We would have written it off to random premature tube failure if
we hadn't noticed that it only happened when we used that particular

graphic. (It didn't always happen then, the phasing with the other PA had to be just right too, and that varied with filterplexer temperature.) That drove one PA into a negative resistance region of the screen, and allowed it to respond to that particular drive by breaking into oscillation.

Our current Harris Gold line also had an oddity which didn't show up in factory testing. In the middle of the night, it would exciter fault for no apparent reason, indicating high exciter VSWR. We finally tracked it down to a momentary brownout on a *single* phase of the 480 3 phase powering the solid state PAs. Because of the way the multiple solid state PAs are powered and combined, that made the exciter see a high impedance load and fault. It only happened in the middle of the night because that's when Ga Power was doing a particular load reconfiguration at the substation. It wasn't an oscillation, but it was a fault that Harris didn't find in factory testing. (They reconfigured the PA combiners so that a momentary single phase brownout wouldn't do that anymore.)

The point is that test as you will a priori, you can never be sure you've covered every possible condition that may arise in the field. So to claim that there is *zero* chance of a parasitic or other fault in the field is hubris.

Message-ID: <E1yKMp.418@twisto.eng.hou.compaq.com>
Source record: 100037

>Anyone have plans for a dummy load for up to 150 watts?

You'll need a 1-qt glass pickle jar, empty and washed, with a metal lid. You'll need a quart of baby oil, a chassis-mount SO-239 connector and 36 each 47-ohm 2w resistors.

You will make six chains, each one containing six resistors in series, then solder the chains in parallel and connect them to the SO-239 connector. You will need to make a hole in the lid, and remove the plastic and paint around the hole to install the connector. Shorten the leads of 4 resistors and only one lead of 2 additional resistors in order to make a six-resistor chain about twice as long as the height of the jar. Solder the chain together and after it's cooled bend it around in a loop and put it in the jar to see how it will fit. When you're satisfied with the lead lengths, make five more like it. Solder the chains together in parallel so only one lead is on each end, and solder these two leads across the SO-239.

Make sure the jar is absolutely dry.

Now the assembly is hanging from the lid. Insert the whole works carefully into the jar, to make sure it fits and nothing touches together that shouldn't. It's OK if leads in one point of a chain touch leads in the same point of a different chain because they're at the same voltage. An ohm-meter can verify the resistance to be 47 ohms. Technically we should be using 52 ohm resistors but 47 ohm resistors are much easier to find and close enough for most purposes.

Now pull the assembly out of the jar and if you want this to be leak-proof, take this opportunity to seal around the SO-239 connector with caulk or RTV. Pour bottles of baby oil into the jar, but allow enough space for the resistor chains to be put back into the jar. You might want to finish filling the jar after inserting the resistors back into the jar, holding the jar lid open while pouring in the last of the oil. It's not important to fill the jar completely, only to fill it up enough to cover all the resistors in oil.

The dry dissipation of each resistor is rated to be 2w, so immersed in mineral oil (baby oil) the whole works should be able to dissipate 288 watts. My rig is barefoot so I made a dummy load from five strings of five resistors each rather than six by six.

I never sealed mine around the connector, just screwed the lid
on tightly and tried to keep it upright at all times. So
far it's worked out OK.

>liable to oscillate at some place where it is not resonant. You're
>contradicting some pretty well known facts and principles there, Wes.

No, I'm not contradicting any well-known "facts".

The requirements for sustained oscillation are that A*B=1

where A is the amplification factor and

B is the transfer characteristic of the frequency-selective network,

which results in the requirement that the product of A*B must have a magnitude of 1 and a phase angle of 0 degrees.
(REF: Electronic's Designers' Handbook, 2nd edition, edited by L. J. Giacoletto, p 16-13.)

NOTE: there is NO requirement that anything be resonant! For example, a phase shift oscillator can be made with an inverting amplifier and three or more cascaded RC networks which provide an additional 180 degrees of phase shift. Please try to find the resonant frequency of this circuit with your GDO.

Even most crystal oscillators do not operate at the EXACT crystal resonance. Instead, due to non-ideal phase shifts in the active device, the frequency of oscillation shifts slightly to a point where the phase shift through the crystal and associated components makes up for the non-ideal device. BTW, most hams believe that crystals operate at either their minimum (series mode) or maximum (anti-resonance) impedance. As the foregoing states, this is not necessarily the case. A crystal oscillator is stable because of the crystal's very steep phase vs frequency slope, not its point of minimum loss. But, I digress....

Learning that there is a spurious resonance some place DOES NOT mean that this is a point of instability. If the loop gain is low enough, the system does not oscillate. Period. Conversely, it the feedback phase shift is correct (or incorrect in this case) and the loop gain is greater than one, we have oscillation.

>circuits where attaching virtually anything conductive to the circuit
>will compromise the measurements.

OH? Tom R posted data from a "specific case" which you challenged and I
defended, both specifically and generally. Indeed, EVERY measurement perturbs
the device under test to some degree, even your GDO. The beauty of modern
network analyzers is that the pertubation is quantifiable. For instance, I
can and have measured transistors that have an input reflection coefficient
greater than one. This means that if you were talking about reflected power,

more is coming out than you are putting in, or expressed another way, the resistive component is negative.

In my measurement circuit, the device is stable, not oscillating, and therefore, I have highly "peturbed" it with the measurement system. This does not mean, however, that I can't predict how it will perform in another circuit. In fact, with the known data, I can compute how prone to oscillation an amplifier might be which used this device. Will your GDO predict this?

>In my opinion, a GDO with no physical connnection, and with care not to

Of course not. Nothing has an infinite impedance. As I stated above, the "invasiveness" can be accounted for.

>If yes, then I have no problem with his measurment technique. If not,
>then his network analyzer IS affecting the data. If you don't know,
>then you are (again) telling us more than you know. (still not a wise

No again. The network analyzer is affecting the circuit but it is not affecting the data. The data are corrected for the effects of the measurement system.

Hi Wes,

Without drawings it's pretty difficult to explain how to measure a PA. But factually, even if someone "see's a real sharp dip", it means nothing at all in operation of the PA. It certainly does not indicate the likelihood of oscillation.

The whole exercise is just another way to support claims that aren't true.

In article <n7ws.208.0022535B@azstarnet.com>, n7ws@azstarnet.com (Wes Stewart) writes:

Tom Brown:
>>Of course, you maintain that "the whole staff" at Eimac agrees with you,

>>Oh, and I asked before.....what is Mr. Brandon's official title at
>>Eimac?
>
>Spurious arguments. Wy bother?

Let me say why we should bother Wes. Rich's intentions may be good, but he is absolutely giving false information about how a tube operates, and how it fails. He has taken a situation that was found in one UHF high power triode, and applied it to other tube types. His descriptions of failures and the reasons for failures is absolutely incorrect.

The delemma is this, in order to prevent engineers from wasting time with unimportant calls, or an employee from providing incorrect information, most companies have a screening process. Engineers channel information through one person, and that person disperses the information to a customer service enginner or technician. At Varian (now CPI), the person in contact with customers is Reid Brandon. The actual engineers are only available to other engineers who have very specific technical questions about a tube, or operation of a tube.

Rich refuses to consider Reid Brandon a good source, even though he is the interface between engineering and the customer base. I did offer to let any two people call a design engineer that is director of a group of tube design engineers, a person who was head of Varian's Power Grid tube R and D group. I also offered John Button, presently a manager at Varian, as additional confirmation.

The reason for this is Rich has made some claims that, ludicrious as they are, can cause people to ruin expensive tubes. These claims also causes people toi falsely believe that parasitics are a major source of PA and PA tube damage, and divert people from finding or understanding the real

causes and cures of problems. This hurts technology, and costs people time and money. It can even cost lives.

W2GO was killed installing an "improvement kit" in a Ten Tec Titan. Al had repeated 3CX800 failures, probably do to the fact Ten Tec did NOT use an electronic overload grifd protection system in that PA. Had Al been given accurate information, his repetitious tube failures might have been cured and he might still be alive. Of course, he might have been killed adding a grid protection circuit also, but at least he would have been doing something to actually cure the problem.

I think it is important to get accurate information out, because there is no reason to put people in harm's way doing needless modifications. Especially when some of the modifications can actually reduce the life of expensive tubes.

Rich claims he is Varian's messanger. Yet all of the people I deal with on a regular basis think Rich's theories are the worst thing that has happened to PA technology to date. Buzz Miklos, a tube design engineer in charge of a staff of 15 design engineers, has offered to donate his time to explaining how a tube fails, and where the parasitic story came from. But he can not do it on the net.

Apparently no one is interested in the truth, since it is not as exciting or sinister as some tall stories are.

Tom B wrote:
>>Did you make the analysis with your HP network analyzer *without*
>>hooking *anything* physically to the circuit under test? If not, then
>>the data you collected concerning the resonant points is suspect.

Tom, the data is not suspect at all. It is the only accurate way to measure the grid's role in shielding. The primary error it is subject to is the tube being cold. This is the one of the very same tests Eimac uses to measure the RF characteristics of tubes.

The beauty of a network analyzer is the anode and cathode can be loaded with the same impedances presented during operation, and the various parameters displayed accurately. The instrument measures Q and other parameters with an accuracy of a fraction of a percent, and loads the circuit with as much loading as desired, from a few ohms to hundreds of thousands of ohms.

It even can allows placement of dc bias voltages and currents on the components while testing. A grid dip meter is the poorest method available to test any of the parameters Rich was claiming to measure, that fact is indisputable.

>Conversely, a parallel resonant situation will do the opposite.

Exactly. As I've said all along, with a GDO we have no idea what the systems impedance or Q is. The user has no idea if the dip indicates a point of enhanced stability, or reduced stability. There is no indication of impedance or Q. A GDO is one small step above a battery and buzzer.

Rich avoids technical questions about Q. Very plainly the conventional parasitic suppressor examples he gave have a Q of about one. Adding nichrome only reduces the Q a few percent, yet Richard claims it cures all oscillation problems. While he accuses me of making smoke, he sidesteps the issue that the parasitic oscillation is at 180 Mhz in the PA I tested.

It's tough to resove something when one of the major players responds to facts with accusations.

I am looking for a low cost approach to stripping 14 conductor ribbon cable (0,050: spacing). I need some kind of tool to strip about 0.1" off one end of the cable. A company named Paladin/Weidmueller made one once upon a time but can't get it in the U.S. anymore. Does anyone have such a tool for sale ? Are there some homebrew versions that anyone knows of ? Any help in this regard is appreciated.

TIA

3672. SbFFT1.2 SB16 spectrum & filtering - BETTER GRAPHICS SUPPORT

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-06 00:00:00 UTC
From: kevinm@eden.com
Message-ID: <5884t7$1s5$4@boris.eden.com>
Source record: 99956

I have uploaded to Simtel.Net:

http://www.simtel.net/pub/simtelnet/msdos/hamradio/sbfft12.zip
ftp://ftp.simtel.net/pub/simtelnet/msdos/hamradio/sbfft12.zip 1558410 bytes

sbfft12.zip Sound Blaster spectral display & filtering

Features:
* Sound Blaster 16 (or 100% compatible) input and output.
* Band widths of 2K, 4K, 8K or 16K Hz.
* Spectral resolutions of 1 Hz to 16 Hz per pixel.
* Display of power spectral density with any of 4 color maps in either
linear or logarithmic scale.
* Define and use up to six filters simultaneously -- band pass, band
stop, low pass, and high pass. Filters have 25 Hz skirts at 3 to 50
dB points.
* Filters are defined graphically by mouse movement based upon the
displayed spectrum. Once you see a signal, you can quickly define a
pass or stop filter around the signal by clicking and dragging the
mouse.
* Net filter passband is displayed at all times.
* Filters can be selectively enabled and disabled by a single keystroke
or mouse click.

Special requirements: DOS 3.0 or higher, SB16 or 100% compatible, SVGA,
VESA 640x480 & 1024x768, mouse, 486/66 or higher to display spectra,
Pentium 120 or higher to filter.

Changes: Differences from version 1.1:
* Compatible with many more graphics cards.
* Full screen mouse support with faster response at high resolutions.
* Mouse click to enable/disable and delete filters.
* Defaults are assumed for the Blaster environment variable.
* Support for PCX graphics files instead of TIFF.

Freeware. Uploaded by the author.

Hi Gary,
In article <1996Dec5.173149.27195@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>Yeah, but what happens if the critical phase is between the steps?

The chance of a stage being hyper-sensitive to small phase steps is pretty remote Gary. I'm sure you know that. Plus the voltage (and hence gain) is increased.

>>It is a fact that any oscillation occuring in the field can be duplicated
>>in the lab, unless the source of oscillation is RF ingress into a low
>>level stage that is not part of the lab tested system.
>
>In *theory* that's correct. But in practice you never test every
>possible condition a priori. That's what happened to RCA with the

>energy at certain seldom used frequencies in the video passband,
>the thing would break into a parasitic oscillation which ate the
>screen grid of the 8916. The fix was a paddle in the cavity which
>broke up that particular resonance mode.

Sure, and and a good engineer would investigate the cause of the instability, because if it happed to you it surely could happen again.

>We would have written it off to random premature tube failure if
>we hadn't noticed that it only happened when we used that particular
>graphic. (It didn't always happen then, the phasing with the other
>PA had to be just right too, and that varied with filterplexer
>temperature.) That drove one PA into a negative resistance region
>of the screen, and allowed it to respond to that particular drive
>by breaking into oscillation.

This is a much more complex system than a conventional PA. Cavity loads and especially parallel PA's are a problem I would never attempt to make a blanket stability claim about. I ceratinly agree with you now that I understand the system, because I have had similar experiences with combined transmitters operating into high Q selective filters. A system like that is a stability nightmare. I am working on a combined system of UHF FET PA's now that is very unstable.

>Our current Harris Gold line also had an oddity which didn't show
>up in factory testing. In the middle of the night, it would exciter
>fault for no apparent reason, indicating high exciter VSWR. We finally

>The point is that test as you will a priori, you can never be sure
>you've covered every possible condition that may arise in the field.
>So to claim that there is *zero* chance of a parasitic or other fault
>in the field is hubris.

Well it's so damn close to zero it might as well be zero in a HF PA, which was the subject at hand. Mr. Measures was speaking of VHF oscillations, and I was responding in kind. They are NOT affected by things downstream of the selective components of the PA, except as those components affect the current and voltage of the PA.

Parasitics in an HF amplifier are a cakewalk compared to combined systems. And remember, the PA problem you witnessed was at or near the operating frequency. It was not something removed several times from the operating frequency.
As a matter of fact Gary, the most difficult stability problems are those which occur closest to the desired operating frequency.

A cavity was involved in the 3CX10000U7 parasitic that Measures tries to tie into small tubes like the 8877. In that case, the tube (operating in a UHF cavity) oscillated at microwave frequencies. The oscillation was a low enough level that it didn't show on the meters, and the frequency was high enough that the sustained oscillation slowly cooked the grid over weeks and months of operation.

The Russians has a similar problem with a larger tube in a cavity. There was even a paper published on this effect (when very large triodes are operated in UHF cavities).

Somehow, this was twisted by Rich into the basis for nichrome in 8877's and such at HF. You and I can argue statistics all day, but while we do that people trying to learn how a HF PA fails will be fed false data. Perhaps your cavity combined TV transmitters will launch a new wave of HF PA parasitic paranoia, even though the systems are as different as night and day from the ones we were talking about. I guess that's what happens when certain personalities are fed information they can not grasp.

So we fully agree on this point. With combined transmitters driving a high Q load and unknown excitation, it is impossible to test for stability with certainty. Even with an unknown cavity, exciter, and a single transmitter, the reliability of any test would be very suspect.

VHF stabilty in an HF amp? No way is that a problem. And I remain solidly convinced of that. The entire RM parasitic theory is pure unfiltered bunk. None of it washes.

73 Tom

Source record: 99966
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.swap,rec.radio.amateur.homebrew,rec.radio.amateur.equipment

I am parting out a Heath SB-102 HF transceiver. Do you need any parts
to repair your Heath rig? Most of the electrical parts are the same in
the SB-100/101/102 and HW-100/101 rigs.

The following parts are NOT available, so don't ask:
- Meter (I do have one with a bad face and good movement, however)
- Plate and load capacitors (I'm using them in a HB 807 transmitter)
- Tubes
- Plate tank coil
- VFO dial (it was shattered already)
- CW filter (put it in another rig)
- Filter selecting lever knob (it was broken anyway)
- Crystals (all have been sold to other Heath owners)
- RCA jacks from rear panel
- Rubber drive belts (they were rotted)

The LMO works, but tuning was real scratchy, indicating either worn out
or dirty bearings on the tuning capacitor inside.

I do have nearly all of the internal parts still available. The front
panel is not in great shape, but it's usable. The markings are faded,
but the paint's not too bad. The cabinet is dent-free and the paint
is in fair condition. Good restoration candidate.

Email me with your parts needs.

Well Tom, I'm happy for you that you live next door to Boeing and can take advantage of the govt's largesse that we're both paying for. Not all of us can do that. I got some of this guys wire, (when he advertised it in the QRP-L) and am very happy to get it. I used to manufacture Power transformers, and we used a bunch of this stuff, and paid thru the nose for it new. I had brought some with me when I retired, but was running low and am happy to be able to buy it at 10 percent of DigiKey and Mousser prices.

If you didn't need it, you didn't have to be snippy about it. Matter of fact, I'll make you a standing offer, make me up 100 foot put ups of the stuff you get, send it priority, and sell it to me cheaper, and I'll buy from you. You too Bill,

W4ZCB

Ok, Tom.. Sorry for the delay, but there were some other issues that didn't appear to wash, which I dealt with first.
>snip,,,

With 70 nH and 100 ohms:
Q = 2.3
...snip...

.....Does Q = 2.3?

This is a parallel circuit, so most things are inverted. (Standing on head may be useful.) Instead of calculating reactance (X), as would be the case for a series circuit, we must instead calculate susceptance (B). . In a parallel circuit, we graph B (with the + and - signs inverted) and conductance (G), (G=1/R), to calculate admittance (Y) instead of graphing R and X to calculate impedance (Y). R is in ohms and G is in siemens. (archaic: mhos) . Using Y=1/Z and Z=1/Y, we can convert a parallel circuit to a series equivalent circuit, or we can convert a series circuit to a parallel equivalent circuit.

In order to be able to use the formula Q=X/R, we must first convert the parallel 70nH/50 ohm circuit (Y) to an equivalent series circuit (Z) by using Z=1/Y. To do this, most everything inverts. BL @100MHz, is -1/(2*Pi*100^6 Hz*70^-9 H) = -22.7 milli-siemens. The G of the 50 ohm R is 1/50 = 20 milli-siemens.

To graph this, the -22.7 milli-siemen BL vector heads down and the 10 milli-siemen G vector heads to the right. The resulting vector forms a right triangle whose tangent is -22.7/10 = -2.27, = -66.22 degrees. The hypotenuse, Y, can be solved with the square root of the sum of the squares. Thus, Y = 24.8 siemens@-66.22 degrees
Using Z=1/Y, , we convert this to an equivalent series circuit whose Z vector can be resolved into its X and R components---the very things we need to solve Q=X/R. Solving for Z = 1/(24.8 millisiemens @-66.22 degrees), Z = 40.3 ohms @+66.22 degrees. The X vector is sin 66.22 degrees (0.915) * 40.3 ohms = 36.9 ohms. The R vector is cos 66.22 degrees (0.403) * 40.3 ohms = 16.2 ohms.

Finally, using Q=X/R, Q = 36.9/16.2 = 2.28. Thus, your answer of Q = 2.3 looks good to me, Tom.
I checked another one of your Q problem's answers, and it looks good too.

Tom: Why did you recently cancel your 28 November post?

3689. Tektronix 491 question

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-06 00:00:00 UTC
From: n1ist@netcom.com
Message-ID: <n1istE2094t.HFx@netcom.com>
Source record: 99973
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

I recently picked up a Tek 491 spectrum analyzer at a flea. It seems to be working fine, but I have one question: How do you calibrate the vertical (signal strength) scale? Short of having a signal generator of known amplitude at the desired frequency, I haven't figured out how. Right now, I'm using it to measure 860 MHz signal strength around the apartment to see how much is coming in from a new SMR site being installed 25' above us...

Also, any recommendations for who to get a user and service manual from?
Thanks and 73.
/mike

> well-meaning, and a GDO has its place, but... This ain't one of them.

I disagree, Wes. Finding resonances and potential frequencies of
oscillation are applications where a GDO excels. It did years ago, and
it still does. If Rich's GDO is not indicating the resonant frequencies
in the circuit, then please tell us what it IS indicating?

If the circuit is NOT most likely to oscillate at one of its resonant
points, then please tell us where it WOULD be most likely to oscillate.
And please include an explanation of just why the circuit would be more
liable to oscillate at some place where it is not resonant. You're
contradicting some pretty well known facts and principles there, Wes.

Why not? If the GDO's dip was deep and narrow before replacing the
suppressors, and it is broad and shallow after replacing the
suppressors, then exactly what information do you have that makes you
feel that the GDO is lying to us? I just don't see where you are coming
from on that one, Wes.

> Spurious arguments. Wy bother?

NOT spurious arguments. Not by a long shot. And the reason "to bother" is that Mr. Brandon has been one of Rich's critics, and Tom seems to put a lot more stock in Mr. Brandon's opinion than he does in Mr. Foote's letter stating his opinion. We know Mr. Foote's title, which is the only real indication of his credentials we have. However, we do not know Mr. Brandon's official title. Therefore we currently have no information about his qualifications to say that Mr. Foote is all wet, beyond the fact that he works at Eimac. Well, so did Mr. Foote. Therefore, logically, we have no reason whatsoever to think Mr. Brandon knows more about what he is talking about than Mr. Foote did. Unless, of course, we knew just what Mr. Brandon's lot at Eimac is. Which is why I asked the question.

You are starting to sound more and more like Tom. When you start telling other folks what they do and don't have an understanding of, you are (to borrow a phrase from Paul Harvey) telling us more than you know. Not usually a wise practice.

> transmission through the tube.

Wes, you have taken my comment that was specifically focused on *this* case (assessing the resonant frequency and relative Q of the PA cicuits) and applied it to test and measurement in general. That is not what I said or what I meant. The fact is that there are some cases with some circuits where attaching virtually anything conductive to the circuit

will compromise the measurements.

In my opinion, a GDO with no physical connnection, and with care not to
over couple the GDO into the circuit, is one of the least invasive ways
to measure the resonant frequency of the circuit IN THIS CASE.

What kind of network analyzer would be less invasive than that? You are
the expert on modern network analysis (you told me so). Please
enlighten us.
>
[snip]

Would the analyzer that Tom used present an infinite impedance to the
circuit under test AT THE POINT OF CONNECTION?

If yes, then I have no problem with his measurment technique. If not,
then his network analyzer IS affecting the data. If you don't know,
then you are (again) telling us more than you know. (still not a wise
practice)

3691. QST 1/97 multimode project

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-06 00:00:00 UTC
From: Nicholas Geovanis <nickgeo@merle.acns.nwu.edu>
Message-ID: <Pine.HPP.3.93.961206132606.17623A-100000@merle.acns.nwu.edu>
Source record: 99975

Hi all --
(WARNING! WARNING! Question from electronics dilletante!)
I copied the January QST article describing the simple RS232-attach
multimode decoder. Looking at the schematic, I thought, "This is so
simple, even I might be able to figure out how it works." So...
Does the term "limiter" mean the same thing as "clipper"? Looks to me like
all this thing does is "clip" the audio waves at a level useful for RS232
(what, isn't that +13 V. max or something), and the HAMCOMM or whatever
software samples the DSR line, (hopefully) alot faster than the signal. Is
this a fair description or is it totally stupid? So, if I can decode CW,
RTTY, Amtor and WEFAX with $10 of parts, a PC and shareware, why the hell
do MFJ, AEA, etc., charge hundreds of dollars for their decoders?
Thanks...Nick G.

>
> Gary
> --

Very interesting, Gary. Is hubris is a factor in this fracas? When a guy becomes a self-appointed self-annointed "recognized amplifier expert" in QST magazine (p.71, 9/94), he has to defend himself absolutely, positively, 100% of the time. For instance---I worked the parallel Ls-Rs suppressor current division problem that Mr. Rauch proposed (70nH, 100 ohms @161MHz). The results showed that Mr. Rauch's statement about insignificant VHF current flowing in Ls is not the case. In fact the current in Ls was a bit more than the current in Rs. Instead of conceeding this one, Mr. Rauch started backpeddling.

To me, Gary, the most fascinating thing about hubristic persons is that they become their own character-assassins. For instance---: If Richard Millhouse Nixon had gone on TV the morning after the Watergate Breakin and said: I ordered the breakin.....Nixon would most probably have fared far better.

I guess it depends on what is meant by "better". Are you confusing
"better" with "technically more skilled"?

Is a unlicensed driver who builds his own car and drives 100 MPH in
school zones a better driver than one who just buys a car and follows the
law?

If the guy runs the PA into dummy loads, and is only trying to learn, he
definately is the better hobbiest. Of course, that is unlikely.

If he uses the PA on CB, or worse yet sells them or uses them on ten
meters (without a license) or commercial frequencies, helping him is
idiotic. This seems more likely.

Steve, do you really mean iron powder slugs for VHF?

Not being picky but it may ID them better for you.

You might get what you need from Coilcraft.

Coilcraft
Cary, IL 60013

312-689-2361 I think the area code has changed.

Some years ago they sent me an engineers kit that
included all kinds of coils with extra slugs.
It they still exist, try 'em.

Here is what I had in mind Michael,

I can make a continuous tuning dial with slotted wheel,opto's, op-amp and
four other chips. Fed into a microcontroller, the up down signals give you
range.
The micro knows the frequency desired (presets and dial increments) and
the
actual since it displays it.Use an 12 -16 bit R/2R D/A (Grand
simplicity:-)) and let the micro feed the D/A to lock (not hardly) the
frequency. A half million corrections per second should stifle any drift.
Ha ha But can you imagine the AWFUL phase noise from such a design at that
speed? A good VCO is of paramount importance
here.

>Thanks...Nick G.

Yeah, its basically a level converter which causes a serial interrupt
each time the sine wave crosses the voltage threshold, I believe.
These interrupts are counted to get the frequency.

Sure you can use a $2000 computer (or oven a $6000 one) to do the same
job that a $200 multimode controller will do. In fact, I've built the
HAMCOM interface and played around with HAMCOM 3.0 and JVFAX 7.0 for
hours on end. It was pretty neat. Kept me up late many evenings
looking at AMTOR/SITOR, RTTY, SSTV, FAX, etc. Even gave someone a new
state toward his WAS RTTY. I've also played with a BAYCOM for VHF
packet.

How well it detects might be one of the things that makes it not so
handy as an "appliance" controller. The fact that it doesn't do any
of the more advanced HF digital modes like PACTOR, CLOVER, etc. is
another. Having to tie up your multitasking PC to be running only
HAMCOM might be a concern too. But, by all means try it out before
spending the bux. HAMCOM is a very slick program.

You must like to distort facts Richard.

I never suggested 161 MHz, you picked it. It really isn't my fault the PA
oscillates higher in frequency, is it?? Instead, you right away go into
the well known RM attack mode, and once more claim anything disagreeing
with you must be false.

The whole exercise is a waste of time. You are trying to focus on one
statement I made, that the primary path for VHF currents is through the
resistor, and the primary HF path through the inductor. I'm afraid that
statement was too much of a generalization, but even as such it does not
mean you theory about VHF Q is correct.

The Q of the suppressor in question is about one at that frequency. Adding
the magical nichrome to the inductor lowers the Q and insignificant
amount, especially at the frequency where the PA really oscillates. Why do
you avoid this fact?

Nichrome makes an insignificant change in Q of the suppressor at the
frequency of oscillation.

As we can plainly see, I did post three names of Varian engineers who totally disagree with Richard (Reid Brandon, Buzz Miklos, and John Button). Of the three, Miklos is the most technically inclined, since he actually designs tubes and oversaw the entire staff in R and D at Varian. He presently heads a group of about 15 engineers at another tube manufacturer.

Contrary to your claim, there were names posted and an offer to repute Measure's claims. Also contrary to your claim, it was explained what Reid's position is. Rather than taking up room, you can call CPI and ask THEM what Reid's status is. Let's not make a lot of noise over nothing Tom.

Many people wrote QST and/or commented negatively on Richard's claims to QST. According to QST, they had a stack of letters an inch high from people disagreeing with Measures. Not satisfied with that, QST sent Richard's work out to at least half a dozen experts in the industry...*** these were NOT the people listed in the QST's technical retraction. *** As I understood, QST could not find a single person supporting Richard technically although they looked for months, but that's just hearsay. But at Rich has you, hi.

Ex-varian employees and present varian employees like Dave Chazen, Bill Orr, and Jim Aurand have commented strongly against the parasitic theories, as did industry experts like Warren Bruene and RF Design's editor Gary Breed. Of course ETO's Dick Erhorn, Collin's Warren Bruene, and others not named disagreed also.

Enough of that, if you think it's so important, call Buzz, Reid, John, or someone and check it out yourself. I told you that a month ago. On to technical issues....

I indicated why a network analyzer is much better, and why the GDO is almost useless. Would you like me to repeat the reasons? Would you prefer to talk about the reasons given? For example I mentioned that the GDO does NOT indicate impedance or feedback in a system. You seem to not receive answers that are clearly posted, are you having E-mail trouble?

Tom States: "In my opinion, a GDO with no physical connnection, and with care not to over couple the GDO into the circuit, is one of the least invasive ways
to measure the resonant frequency of the circuit IN THIS CASE."

I may be stepping into something that is out of my league, but it seems to me that the "physical connection" argument smacks of religeous fantasy. There was a time when virtually all significant RF coupling was done inductively--and even today's most advanced solid state power amplifiers transfer huge amounts of power in this manner. If I were to connect you to a powerful 160 MHz source, Tom, would you rather it be through a .5 pF capacitor with a 10 Meg resistor in series--or through a large inductive link with a high co-efficient of coupling. Your choice!

The fact is, with a grid dipper, I don't think I'd have a clue how tightly I am coupling to the DUT--save by assessing the shapness of the dip itself. And, any time the GDO is seeing something, it is also loading something--or the indication wouldn't be happening. I may be stupid, but I guess I just can't quite grasp where you're coming from!

Hi--

I wrote a short piece on PIN TR switches in Winter '95 Communications Quarterly (P66) that may provide some helpful background. It was for low power TX switching, but might add something to your search for information. The basic priciples are the same--although the QEX article would be a lot more specific for cookbooking something in the 50-W power range.

I have tested anode circuit VHF resonances that were so sharp, they sucked the dipmeter out of oscillation. To me, that indicates more than "nothing at all".

Has Tom ever looked at a gold-sputtered grid through a microscope? It's a wondrous sight, what with the cathode sprinkled with a hundreds of tiny gold melt-balls, cooled blisters of once-boiling gold on the grid, and the grid's base metal stripped of gold plating.

> The delemma is this, in order to prevent engineers from wasting time with

Translation: Unimportant Calls: Owners of amplifiers whose bandswitch contacts mysteriously burned up, phoning amplifier manufacturer.

> Rich refuses to consider Reid Brandon a good source,

I don't consider a person's title. I consider what a person says. So far, we have not seen a letter from either Mr. Brandon or from Mr. Button. So far, neither of these gentlemen has shown up on this newsgroup.

> The reason for this is Rich has made some claims that, ludicrious as they

> W2GO was killed installing an "improvement kit" in a Ten Tec Titan. Al had repeated 3CX800 failures, ...

snip,

Assuming it was an AG6K low vhf Q parasitic suppressor retrofit kit, the instructions warns customers:--- "Amplifiers that are plugged into the electric-mains contain lethal voltages, whether they are switched on or switched off! If you don't pull the electric-mains plug before working on your amplifier, your amplifier may be for sale at a ï¿½silent keyï¿½ estate sale!! "

A. Prose Walker, W4BW, had similar problems with his Titan. Ten Tec was not able to resolve the problems, so Prose contacted me. He described the problems. I told him such problems might be caused by an intermittent oscillation condition. Prose installed low VHF-Q suppressor retrofit kit s/n1451 in Sept. 1990. After a while, Prose contacted me and reported that the previous problems had not yet reccured. Prose wrote to Ten Tec's President, Jack Burchfield and told him of the apparent solution to the problems which Ten Tec had not been able to resolve. Mr. Burchfield replied and said that even though he had read Mr. Measures' articles in QST magazine with "great interest", when low Q suppressors were tried, they became "very hot" during 10m operation. Apparently, Jack did not read the instructions to adjust the inductance of Ls to obtain moderate heating on 10m. IMO, if a VHF suppressor doesn't get hot at 29MHz, it is not going to work optimally above 30MHz.
I worked on a Titan in which both 3CX800A7 tubes exhibited gold-sputter leakage after about 25 hours of operation. The operator had been a ham for over 20 years, and he knew how to tune up a grounded-grid amplifier. The glitch that occured at the time the tubes were apparently damaged, did not occur during tuneup.

snip

>
Eureka. ..... There it is, Tom Brown "as much loading as desired". Mr. Rauch has been adjusting the NA's resistive termination controls to whatever HE presumes is appropriate. I wonder if this is how Mr. Rauch determined that no significant VHF current flows through a VHF suppressor inductor, Ls.

Jeez, What a bunch of Crap! I can Buy All The Schematics I Want, I thought maybe Fellow Hobbyists would be Kind enough to help me out! I can Also buy all the Amps I wish! Its not like you would have been giving me something that cannot be aquired elsewhere. I was just looking for a little Help, Something I guess most Amateur Operators are unwilling to do these days!

I know Jay, he's a DECENT person, I'll get them from Him. I currently Have amplifiers! I just wanted to Build a couple with 4CX250's and 6146's. As for being unliscensed I'm currently Scheduled To take my General Class exam in January, Yep January Soonest it can be done because I live in a tiny town, and thats the first available testing without driving 110 miles one way! Maybe if a few of the local Amateurs would Donate some time It could have been sooner! Well I guess they are like Most of you on this newsgroup! Unwilling to help Or they have the nose up the Butt because someone is currently not In a call Directory!

All I wished to do is build a couple Amplifiers. Yeah, Big Deal!!!
I'm stupid to think you Fellow Hams would be willing to help someone who wishs to Home Brew Their entire Station, Not everyone has the funding to run out and buy A Nice Shiny new Amp for the Shack, Maybe, just Maybe, This was a legitimate request From A TO BE Amateur radio Operator Who wishs to get started on Putting my Station together! Now I realize Why this Hobby is Stagnating!

Maybe someone Could Email me and See Just what my intentions were! instead of Jumping up and down and Searching the current Call sign Database to see if I was Present! Well I beleive it would take a while for me to show up in it anyway. But Right Away.....

FELLOW NEWGROUPIES, THIS PERSON DOES NOT APPEAR TO BE
CURRENTLY AMONG US HE DIDN"T USE A CALL SIGN!!!! SO THERE FORE HE IS GOING TO MANUFACTURE AND USE THESE AMPLIFIERS IN AN ILLEGAL MANNER!
IGNORE FURTHER POSTS BY THIS INDIVIDUAL!!!

SIGNED W0ASS

Yeah, maybe the above individual can figure a way to make QST stop my Subscription, HEY, maybe you could even get the ARRL to turn down my application!!! OR HEY BETTER YET MAYBE YOU CAN GET THE FCC TO NOT ISSUE ME A TICKET!!! WOW!!!! MAYBE YOU COULD EVEN GET THE FCC TO ISSUE YOU YOUR VERY OWN FREQUENCY WHERE , NO,NEW,HAMS,ARE,ALLOWED!!!

MAYBE HE COULD EVEN GET THE LIBRARYS TO REMOVE MATERIAL ON LINEAR AMPLIFIERS SO NO ONE COULD OBTAIN IT!!

Sorry for the Wasted bandwidth, I'm sure A number of the people who frequent this newsgroup are indeed fine folk, then we have the other parties who wish to dedicate/validate an existence by policing these newsgroups for unacceptable practices!!

One other thing, I have a Ranger, A Valiant, And soon A Viking 500, they have 11 meters in them. If I wished to run illegal amounts of power on 11 meters it would not be difficult. I could probably even buy a good sized solid state amp. I however have the heart Of A True BA'er. And wish to Home Brew my own Amps, I do have a few Sweep tube amplifiers lying around, yep, even a couple CB radios. I however do not use these. I love the old Tube Equipment And will continue to purchase/build it. And in January I will be on the BA nets And buy then I should have already built either the Single tube 6146 amp or the 4cx250 amp! So you see with or without any help from here THE WORLD CONTINUES TO TURN!!

Hope to Talk With Some Of the Finer operators out here, Listen for me With the other AM Boat Anchor Operators come January!

Unlike Some Amateur Radio operators I will do my best to create interest and enthusiasm for Amateur Radio! If someone asks me for Help, I will help.

73, all, God Bless, And hope you ALL have a good Holiday season!

Rob.......

The amplitude scale is strictly relative, unless you do use a calibrated source as reference. That's the downside of the 491 as compared to the old HP141T systems. On the other hand, the 491 is smaller and lighter.

> Also, any recommendations for who to get a user and service manual from?

Buy one from Ed Matsuda (619-479-0225). He may or may not have an original, but his copies are of good quality and his prices are reasonable.

Hi Richard,

Instead of more RM style personal attacks and non-technical comments about the other Richard we all know of, I'd like to see you answer questions about Q.

I think your parasitic theories are absolutely wrong. VHF Q does NOT change significantly with the addition of nichrome, and that is a fact you are trying to avoid. As a matter of fact, a small adjustment in the suppressor resistance and inductance makes a larger change than the addition of "nichrome".

You realize if the nichrome in the suppressor's winding of wire does not significantly lower VHF Q, then everything you attribute to VHF oscillation must be a product of vivid imaginations, or directly attributed to MY claim that HF Q and mistuning / overdriving are the major causes of arcs and sparks in the tank.

Let's make an agreement.

If I can not lower Q (using coventional components) the same amount or more at VHF without adding as much loss of Q on ten meters as the nichrome does, I will concede you have been hawking something of ### great technical merit ###. I will endorse your product as a good method of parasitic suppression.

If the system you hawk does NOT significantly reduce VHF Q at or near the frequency of oscillation (let's say between 140 and 200 MHz) compared to what I can do with conventional components, will you admit the VHF parasitic cures and theories you have been making are false?

This sounds fair to me, since you claim to have re-discovered the only cure for VHF parasitics.

Hi,
Name here is Gerry (WD4BIS) and I have been writing a column for our club newsletter called "New Ham Partner". With the influx of No Code Technicians on the repeater, asking the same kinds of questions I asked 20 years ago, I have been trying to answer them.
Some of the articles are technical, some of them are general information, but they all address subjects that our new friends are struggling with.

I have set up a web page for these articles. On this page, I will place the columns I have already published in past issues of our newsletter. Doing this on a web page has advantages, the big one being that the articles wont expire in a newsgroup, I can edit old ones or add new columns as write them, and I wont have to send re-posts.

The Cost... I will ask that you do not edit the articles, and use my by-line. If you use them, send me an E-mail and let me know when and where. If you have a spare stamp mail me a copy of your newsletter to the address on the page.

Where... http://web2.airmail.net/gerryc/newham.html

Please bear in mind this site is still under construction and not all of them are there yet, but they soon will be. Some of the URL's arent resolving yet and some in reformating the text are doing funny things. But I am still working on it

Mike, I also have a tek 491. It's OK but as you say, it's only
good for relative measurements. so you'll need that generator for
absolute measurements.

Anyone have a double handfull of the old feedthru caps? The kind that have a 1/4-28 threaded shank, a wire going straight thru the body, and something like a 3/8 x 1/4 hex head on the outside containing 500-1000 pF of decoupling capacitor?

Probably can find them at my next hamfest, but that's couple months off and this project isn't.

3717. Parasitic Suppressor Q

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-07 00:00:00 UTC
From: n7ws@azstarnet.com
Message-ID: <n7ws.217.004121D0@azstarnet.com>
Source record: 99906

I have tried to follow the raging discussion over the merits (or non-merits)of parasitic suppressors constructed with nichrome wire. Frankly, it has been tough to follow at times because the discussion has been cluttered with other topics. So, a new thread, dedicated to a single topic. (We live in hope)

To date, I have seen no one present either modeled data or actual measured data acquired using *appropriate* instrumentation. I have had email discussions with Rich Measures which lead me to believe that he will be send some hardware my way which I will attempt to quantify using my Boonton 250 RX meter. This could be tough because of the low Q, but we shall see. If this doesn't work out, I will report same.

Additionally, I have used both ARRL Radio Designer (ARD) and Mathcad to try and model the effects of nichrome on parasitic suppressor Q. To date, I can come up with no "magic" properties for these suppressors. This is not to say that there are none.

One problem with nichrome (computationally speaking) is that it is a magnetic material. In my limited searching of references, I haven't found a good value for the relative permeability, which along with the resistivity affects the skin effect losses of the wire. However, unless this is non-linear (could be), there is still seems to be no magic involved.

The higher resistivity and permeability of nichrome (whatever the values) simply increase the skin effect losses in the same fashion as in copper or any other conductor.

An inductor wound with nichrome has higher loss (lower Q) than a similar inductor wound with copper, but in the parasitic suppressor, the parallel resistor has the exact effect. In other words, the series equivalent R+jX has an equivalent parallel G-jB which can be made to look the same by addition of external parallel conductance (resistor) to a higher Q copper wire inductor.

The only positive effect I can imagine arising from the use of nichrome suppressors would be due to some non-linear phenomenon that increases VHF loss while not affecting HF loss. If someone can point us to a reference which describes this behavior it would be appreciated and might settle the arguement.

Food for thought, respectfully submitted,

Wes -- N7WS

Hi,

Looking for a chassis mount 5-25 NPO ceramic trimmer capacitor. The part that sticks thru the chassis is 1/2 inch in diameter. Am trying to repair a Collins VFO.

Thanks, Conrad

Whew is right, Wes. Thanks for the heads up. Sorry. I forgot that for a parallel circuit, the formula is Q=R/X. So how do we figure total Q when the parallel Ls contains series R of its own?

I'm still trying to figure out why Tom Rauch cancelled his post of 28 November.

Tom: 30 inches is a quarter wave. The feed Z at the ground end of a quarter wave antenna is roughly 35 ohms. Are you saying that "<100 ohms" is the feed Z at the top end of a quarter wave?

A question: What is the inductance of a six inch wide, flat, thin copper-conductor, 12 inches long?

First, compute the parallel equivalent of the series RL alone.
Then add the parallel resistance using the usual formula for such things.
This gives the new parallel equivalent R||L. Q is computed as above.

They don't know what they have, or at least don't care. That's why it's so cheap. Nothing really great stays around long enough to put in a catalog. (Sometimes they do have catalogs for bid lot auctions).

They were or are closed Monday, and the best pickings were on Tuesday. It's kind of strange to be out in the parking lot in an industrial park on Tuesday morning watching the crowd form. Usually about 50 to 100 techies, hams, machinists, all waiting for the doors to open.

Pickings can be very variable. Sometimes it's just old drill bits, office desks, computers and chunks of aluminum, sometimes you find the widget you've been looking for for years.

>link with a high co-efficient of coupling. Your choice!

This is another area where Mr. Brown and Measures obviously do NOT understand what they are doing.

The very requiremnt that current is removed from the oscillator, causing a dip, indicates coupling is VERY high! The oscillator coil in the dip meter has such high resonant currents that it has a very intense field.

The coupling is so high it actually robs the oscillator of current, cause a dip to appear on the indicator.

I can measure the field from my GDO almost ten feet away with the probe of my network analyzer, yet the GDO has "no idea" the NA probe is there!

It's kind of like the difference between using GPS or a compass, isn't it?

Rich, you allude I adjust the resistance "to what I want". That statement is idotic when we look at the facts.

You couple a GDO to a cold tube that appears as only reactances, when in operation each element has a very finite resistance. For example, negative feedback and other effects combine to make the cathode have a low resistive part in it's terminal impedance and alos greatly reduce the anodes resistive component (at idle it can be taken as Ep/Ip, although it varies over the plate current cycle).

I use the mean impedance of the element while the tube is conducting as the test resistance, while you use an open circuit. Your test is fine if you never power the tube up. When you adjust the tank components, do you terminate the anode in a resistance equal to the operating resistance given in a Chaffe analysis, or do you just leave the anode hang loose?

I find it remarkable you always seem to find fault with correct proceedures while using the worse methods possible in your tests.

What about Q, how much change does you nichrome make at VHF? Is it a large cahnge, or insignificant?

Not sure if it does reversals Carl, we outsource our boards so I have not looked into doing negatives. Running the latest version on my P5-75 it is very fast, but then again I am not designing 200+ pin boards.

> addition of "nichrome".

Since our telephone conversation of 1990, I have been aware that you have a different opinion, Tom. However, you appear to base your opinion on the assumption that insignificant current flows in the suppressor inductor, Ls. When presented with the calculations (from your own Ls-Rs-f I-problem) that similar VHF currents flow in both Rs and Ls, you proffered a plethora of seemingly unplausible arguments to the contrary.

> You realize if the nichrome in the suppressor's winding of wire does not
> significantly lower VHF Q, then everything you attribute to VHF
> oscillation must be a product of vivid imaginations, or directly
> attributed to MY claim that HF Q and mistuning / overdriving are the major
> causes of arcs and sparks in the tank.

I do not realize that resistance wire (nichrome) has no effect on VHF-Q. I have realized that the observed dips in amplifiers' anode VHF-resonant circuits is rather different when silver-plated strap suppressor inductors (Ls) are replaced with resistance wire suppressor inductors. With silver conductors, the dip is sharper and deep. With the resistance wire suppressors, the dip is broader and shallower. This is nothing new, Tom. Mr. F. E. Handy was aware of this technique 70 years ago.. You can read about it in the 1926 Edition of the *Radio Amateur's Handbook*. You can read about it in the 10/88, 9/90, 10/90 and 1/94 issues of *QST* magazine. There's an article about calculating values for VHF parasitic-suppressors in the 3/89 issue.

> Let's make an agreement.

I am reluctant to make an agreement with you, Mr. Rauch.

> If I can not lower Q (using coventional components) the same amount or
> more at VHF without adding as much loss of Q on ten meters as the nichrome

An endorsement from someone who dismisses well-established AC circuit
analysis, who purports that dipmeters are incapable of finding resonances,
would amount to an UNendorsement.

For years I have been using the soldering iron that I bought from RS which has screw in base heating elements in various wattages from 10 to 30 etc. Now of course they no longer handle the screw in base elements. Does anyone know what brand the original was (Weller, Wahl, etc) and if the replacement elements are available anywhere? The base is about the same as a 110 VAC Christmas tree bulb.

Thanks & 73

***EASY MONEY - FAST !!!!!

THIS IS THE FAIREST MOST WAY HONEST WAY I KNOW TO SHARE THE WEALTH !

Would you like to make thousands of dollars, quick, legally, with NO CATCH? then keep reading......please take 5 minutes to read this article it will change your life, just like it did mine.. it's true! you can make up to $50,000 in 4 - 6 weeks, maybe sooner!

I SWEAR I'M NOT LYING TO YOU.AND THIS IS NOT A SCAM! if your interested then keep reading;if your not, i apologize for wasting your time.

this is my second time i am doing this. the first time was 7 weeks ago and i have received $48,000. the first week i received $37 dollars,the second week i received $1,364 dollars and by end of the 3rd week i had received $12,856 dollars and to this date i have received $48,074 and money is still coming in.

when i first saw this article i though it was some kind of scam, but for $5 dollars and 5 stamps i thought i would give it a try.after buying a new car,new computer and putting a down payment on a house i relized this was the best $5 dollars i ever spent!

this process is very simple, and it consists of 3 easy steps:

(this whole process will take only a few hours of your time)

STEP 1: get 5 separate pieces of paper and write the following on each sheet of paper..."PLEASE PUT MY NAME ON YOUR MAILING LIST.YOU ARE NUMBER 4." get 5 $1 dollar bills and place one inside of each paper that you just wrote on,and fold each piece of paper so the bill will not be seen in the envolope (otherwise,nosey people who like to steal envolopes with money in it will get yours). put one paper inside the envolopes and seal it. do the same for all 5. you should now have 5 envolopes sealed,each

with a piece of paper and a $1 bill stuffed inside the paper.make sure those words that were stated above are stated on each paper. what you are doing is creating a service by this, this is PERFECTLY LEGAL. now then, mail the 5 envolopes with the paper and $1 dollar bill in each to the following addresses:

1. Dan Wood

1201 #A Anderson ST

San Clemente, CA 92672

2. S. Stapleton

6329 HWY 135 N.

Lake City, AR 72401

3. C. Crafton

1231 SW 61st Terr. #2

Gainesville, FL 32607

4. Michael Barratt

27 Park Ave

Poughkeepsie,NY 12603

5. Louie Page

2907 W. Gregory

Chicago, IL 60625

STEP 2: now take the first name off the list that you see above, move the other 4 names up (5 becoming 4 , 4 becoming 3 ect.)and put your name as number 5 on the list. you can slightly alter this article if you need to, editing what you need to edit.

STEP 3: post your amended article (with your name at number 5 of the list) to at least 200 newsgroups (i think there are 18,000 of them). all need is say, at least 200. HOW TO DO THIS: IF YOU HAVE NETSCAPE DO EXACTLY THE FOLLOWING:

1) click on any news group like normal,then click on "to news",which is on the far left when your in the newsgroups page. this will bring up a box to type a message in.

2) leave the newsgroup box like it is, change the subject box to something flashy like, "NEED CASH $$$" ,"READ HERE $$$" or "FAST CASH $$$!!.

3) tab once and you should be ready to type. now, retype (only once) this whole article,execpt to insert your name at #5, and remove #1 off the list, plus any other small changes you think you need to make, keep almost all of it the same.

4) when your done typing the whole article, click on file in this box, right above send, not where it says netscape news on the first box. click on "save as" when your under file. save your article as a text file to your c: or a: drive. do not send or post your article until you do this. once save move on to number 5 below.

5) if you still have all of your text, send or post to this newsgroup now by just clicking send, which is right below file, and right above Cc: .

6) here's where your going to post all 200. ok, click on any news group then click on "to news", again in the top left coner. leave the newsgroupss box alone again, put a flashy subject title in the subject box, hit tab once your in the body of the message, then click on "attachments", which is below the subject box. you will get another box to come up. click on "attach file" then find your file below that you have saved; click once on the file,and then click open' now click on ok; if you did this right , you should see your file name in the attachments box, and it will be shaded.

if you use explorer its just as easy.... holding down the left mouse button,highlight the article. then press "ctrl" key and the "c" key at the same time to copy this article. then print this article for your records to have the names of those you will be sending $1 bills to. next go to the news groups and press "post an article", a window will open. next go to the news groups and press "post an article" a window will open. type your headline in the subject area and then

click in the large window below. press "ctrl" and the "v" and the article will be placed in the window. if you want to edit the article do so and then highlight and copy it again.now everytime you post the article in a new newsgroup you only have to repeat "ctrl" and "v" and press post.

7) THATS IT. each time you do this , all you have to do is type in a different newsgroup,so that way, it posts to 200 different newsgroups ..you see? now you just have 199 to go!! (dont worry, each only takes about 30 seconds once you get the hang of it).REMEMBER 200 IS THE MINIMUM.

THE MORE YOU POST THE MORE MONEY YOU WILL RECEIVE !!!

AND THATS IT !!! THATS THE ONLY 3 STEPS THERE IS !!!

you are now in the mail order business and will start receiving your $1 envolopes from various people all over the world within days. hint: you may want to rent a po box eventually because of all the mail you will be receiving. JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT, PLEASE.

LET ME TELL YOU WHY THIS SYSTEM WORKS !!!!

out of every 200 postings, lets say i only receive 5 replies (which is actually very low!) so i made $5 dollars with my name at # 5.

now then,each person that just sent me $1 makes, say only 200 postings now with your name at #4, which is a total of 1000 postings,not including yours too. 50 people send you $1 now; thats $50.00 you just made! now, then your 50 agents post 200 each with your name at #3,or 10,000 postings (50x200). average return is 500 a $1 each is $500.

they make 200 postings, which is 5,000 returns at $1 each, which is $5,000 dollars! and finally, 5000 people make 200 postings which with your name at #1. you now get a return or $50,000 before your name drops off the list. and thats if everyone only makes 200 postings and if only 5 people respond !!!!

no like me when your name drops off the list just find the latest

posting and start over again..YOU WONT BE SORRY !!!!

ICOM 706 Station including:
IC-706 (Purchased new 16AUG96, never mobile)
AT-180 Antenna Tuner 160m thru 6m
FL-100 500Hz CW Crystal Filter
OPC-581 Seperation Cable
MB-62 Mobile Mount
MB-63 Faceplate Mount
Total AES Price $1901.85. My price $1520.00 plus shipping.

Also have AEA 6 Meter Halo Antenna, about one month old. AES cost
was $69.00, my price $55.00 plus shipping.

All equipment is in mint condition. E-mail me if interested. I am
located in Culpeper, Virginia (about 70 miles SW of Washington, DC).

Yeah...I feel your pain. I'd much rather spend hours and hours finding a replacement tip than buying a whole new soldering iron for $6.99. When I had the same problem I sent messages to several newsgroups and contacted many manufacturers in writing and via telephone.

But I do offer words of encouragment. After several days of effort and several e-mails, phone calls, and letters, I was able to find a replacement element, shipped by Acme, for $12 plus $3 S&H. I figure that if you count the value of my time, plus my expenses, I spent about 650 bucks but it's a hell of a lot better than letting "big business" take advantage of me!

Hang in there!

Hi Tom, the above acid test methods may be okay for a manufacturer of
amplifiers, with a inventory of spare parts. I'm sure you don't mean
for the average Ham to do that kind of test for instability. It could
be very expensive, especially with a out of production SB-220.

>73, Jesse, W6KKT

I once owned an amp (pair 4-1000A's) made by Eimac/Varian. The suppressors were made by winding 3 turns of #10 wire around Carborundum 884 SP500K 50 ohm glo-bar resistors. The clips on the ends of the resistor served as terminals for the coil and the half-inch straps leading from the top of the plate choke to the tube anodes.

My own personal design experiences with the 4-1000A:

When running this tube above 5000 volts on the plate it needs some "taming". Successful solutions were passed down from ham to ham... putting a 10 ohm resistor in series with a 25 pf cap from each filament pin to chassis was the most significant cure for squirliness.

I quickly found that small MOF and carbon resistors that I had used in the past on anode suppressors were quickly "crispy-crittered" when the amp was operated on 10 meters. The suppressor coil did not get hot, the resistor did! Even Varian agrees it takes at least a 20 watt resistor to make a reliable suppressor for this beast. Bottom line: I think the engineers took each new amp design as it presented itself, and did what was necessary to "make it work" by trial and error. (((73))) Phil, K5PC

3743. Where Hi Voltage Zeners?

>Date: Sat, 7 Dec 1996 08:36:31 LOCAL

>To date, I have seen no one present either modeled data or actual
measured
>data acquired using *appropriate* instrumentation.

Not true Wes, I've done that although it gets lost in the needless
clutter.

I measured an AL-80B suppressor at 180 MHz and the Q was 0.80 using an
almost new HP Impedance Analyzer.

> I have had email
>discussions with Rich Measures which lead me to believe that he will be

>try and model the effects of nichrome on parasitic suppressor Q. To
date, I
>can come up with no "magic" properties for these suppressors. This is
not to
>say that there are none.

I've had difficultly locating exact data on nichrome also, mainly because
Richard offers no information as to the size or characteristics of the
nichrome.

>An inductor wound with nichrome has higher loss (lower Q) than a similar
>inductor wound with copper, but in the parasitic suppressor, the parallel

>resistor has the exact effect. In other words, the series equivalent
R+jX
>has an equivalent parallel G-jB which can be made to look the same by
addition
>of external parallel conductance (resistor) to a higher Q copper wire
>inductor.

This was my point all along Wes, and I suspect it is the reason
discussions of Q are avoided in favor of GDO measurements and arguements.

As you said, the truth is adding nichrome in the suppressor's coil is equivilent to adding slightly more inductance, and slightly lowering the suppressor resistor value. There is no magic at all to nichrome, except it lowers the loaded and unloaded HF Q of the tank (mostly around 20-30 MHz).

Nichrome changes system Q very little at VHF, and no more than could be accomplished with a slight readjustment of actual components. If the nichrome corrects anything, it is excessive voltage from improper tuning in the upper HF region. The VHF Q thing is bunk. It's as scientific as the 500 watt grids and damage to tubes on standby from photons.

As near as I can tell by measuring individual components and the system, the 80B suppressor system looks like this at 170 MHz:

Suppressor (coil in place over the 100 ohm resistor but not connected) Q 37.4 L 85 nH. Leads and components from anode to ground ~3 ohms ~100 nH (these readings vary with lead dress).

I measured an anode connector to chassis impedance at 200 MHz of 55.24 ohms in series with 138.97 nH for a Q of 3.16. This tracks closely with a suppressor coil of 85 nH with an ESR of two ohms, and two ohms of lead loss in the path from the anode to chassis.

If I add 10 ohms of resistance in series (to simulate nichrome) with the suppressor's coil, and 6 ohms of resistance to the anode lead (I think I have been overgenerous in adding that amount of resistance, but I wanted to give Mr. Measures every advantage) Q drops to 2.78.

Q drops from 3.16 to 2.78 in this VERY generious example.

The lower VHF Q theory is seriously flawed. That's a real problem, since Mr. Measures claims over and over again it magically cures arcs, sparks, bangs, pops, and melting glass from VHF parasitics.

Wes, if you'd like the actual components used in the stock PA, or a mock up of the related components on the actual chassis, let me know. Otherwise I don't see how you will compare Q. Ameritron uses a special order non-inductive resistor in this suppressor.

> In article <measures-ya023180000412961119110001@news.vcnet.com>,
> measures@mail.vcnet.com (R. L. Measures) writes:

W8JI wrote:
>You have no idea if you are reading grid resonance, or a resonance effect
>in the leads near the socket. ....snip

RM wrote:
>>There are no other leads near grid pin #3.

There were actual components attached to the leads in one condition, and in the other condition your dip meter is exciting one lead that is in parallel with two others through the base of the tube. The grid sees the circuit much differently.

A GDO is the wrong instrument for measuring changes in the grid's effect on shielding. It measures resonance at one point, when we really need to know the impedance at another point in the complex system. The only way to determine the shielding ability of the grid, or the grid's relative impedance to ground, is by passing a signal from the anode to the cathode with the grid interrupting that path.

Resonance tells you NOTHING about the frequency of oscillation. If there is a resonance it might be a frequency where the tube actually tries to NOT oscillate, where it DOES try to oscillate, or neither. Sticking the GDO near the grid pin or lead is a frivolous measurement, it's about as useful as grid dipping the power cord.

On the other hand, the change in transmission loss through the tube CLEARLY indicates changes in shield effectiveness of the grid. Where the grid has a high impedance, transmission loss is maximized. Driving the tube with a source Z close to the operating impedance of the satage, and loading the anode with a value approximating the anode resistance of the stage gives an excellent indication of potential feedback problems.

RM sez.
>>IMO, there is really no such thing as a 'direct-ground' at RF
>> frequencies.
>>Even 6-inch wide copper ribbon has a finite amount of inductance per
>>unit length. At 100MHz, roughly 30 inches of such material looks like a

W8JI said:
> Perhaps you call Z< 100 ohms "high Z". The wider conductor has a lower
> surge impedance, and a lower impedance when resonant. A thin conductor
> would have high Z, but a six inch wide conductor would look like a low
> impedance.

RM sez
>>Tom: 30 inches is a quarter wave. The feed Z at the ground end of a
>>quarter wave antenna is roughly 35 ohms. Are you saying that "<100
ohms"
>>is the feed Z at the top end of a quarter wave?

When the conductor has an L/W ratio of 5 your theory fails. The conductor has considerable capacitance and a very low surge Zo. The resistance of an end-fed 1/2 wl is less than 100 ohms for a L/D ratio smaller than 30 (Characteristics of linear elements, Antenna Enginnering Handbook, Jasik 3-3).

RM asks
>A question: What is the inductance of a six inch wide, flat, thin
>copper-conductor, 12 inches long?

Depends on the frequency, what is around the conductor, and how it is connected. Reactance and resistance varies with frequency. At high frequencies the problem is complex, on some frequencies the 12 inch lead will even be a capacitance.

I'm under the impression you consider conductors simple inductances with no distributed capacitance. If so, that is a mistake.

Mario wording sounds ok to me. It is the technical content that matters,
and he has a good grasp of things. IMHO, that is what matters.

Too many people can write absolute techincal rubbish that sounds perfect.

Mario, the overshoot can trigger a tank arc in a tube type PA. I've seen
this happen often. Under the right conditions, it can be almost as bad as
shorting the output jack!

l) DECADE RESISTANCE BOX'S FOR SALE MODEL 63

Description:
The Model 63 Precision Decade makes possible the selection of any resistor value from 1 ohm to 999 ohm in 1 ohm steps. The resistor elements are housed in a sealed bakelite box and are non inductively wound on porcelaine tubes. This unit is suitable for use in electrical measurements, substitution resistor's to aid in designing and for experimentation in schools and research institutes. Ranges 0-9x units, tnes, hundreds, thousand ohms. Precision .1% resistor elements Manufactured by Brunelle Instruments Inc. Price $29.00 each (Qty only 24 on hand). Manufacturing overrun (NEW).

2) REGULATED BENCH POWER SUPPLY - MODEL 1030

DESCRIPTION:
The Model 1030 is 0-18V, 0-3A, adjustable, dual meters, regulation .01%. TOP QUALITY SUPPLIES (NOT CLUNKERS) Mfg by Instek. $189.00 NEW

3) PULSE GENERATOR - MODEL 3060

DESCRIPTION:
Can be used with an Oscilloscope for adjustable sweep delay, TTL/CMOS LEVEL (output adjustable), built-in Logic Tester, Pulse period range of 100 nS to 0.1S, Frequency range 0.5 Hz to 5Mhz. Operating modes: Run, Trigger, gAte, One Shoot, Square, Invert. MFG by Instek. $159.00 NEW

Source record: 99855

Hello all: Please help. I just purchased a Dentron Clipperton Amp, with 4 - 572B tubes. The amp seems to require a lot of plate current to get going. That is, with 40 watts drive, I get 700 watts out, with 1 Amp plate current being drawn. The high voltage is about 1500 volts. Pretty bad efficiency at about 47%. If I push it harder, plate current goes beyond 1 amp, and arcing begins (arced once anyway). This is in "low" power mode, 1500 volts, if I kick it to high power or about 2200 volts, I can get almost 1000watts out, but with 2200watts in. I cannot drive it harder that say 50 watts or so without plate current going beyond 1 amp input. I can't even back it off with the load or tune. Is this normal for this amp? Will I blow it if I run it at 1 amp plate current in?

Thanks in advance, 73 all, Mike... - WQ0N - email: tenorman@i1.net

Hi Ron,
Sounds like the old Ungar irons. I've noticed that Mouser carries Ungar.
You might try them. (800) 346-6873.

I believe Ungar made the RS soldering irons. The base of the heating
element is in fact the same as a 110v xmas bulb. Makes a handy drop
light in a pinch. The tip I believe was a 1/4"-20 thread.

Check Mouser, MCM, etc. I known I've seen replacement tips that would
work.

Doug,

I think the DGPS beacons operate on different frequencies around the world. Here on the Canadian West coast, we use the navigation beacons in the 300 KHz-range. So, you can use any HF receiver that covers that band (modulation is AM, as far as I recall), but you will also need a decoder to make sense of the signal.

Alas, I can't help you with info on the decoder, but you could try VE7CEI's GPS pages. The URL is:

> are trying to avoid. As a matter of fact, a small adjustment in the
> suppressor resistance and inductance makes a larger change than the
> addition of "nichrome".

Since 1990, I have been aware that you have a different opinion, Tom.
However, you appear to base your opinion on the assumption that
insignificant VHF current flows in the suppressor inductor, Ls. When
presented with the calculations (from the very problem you proposed) which
showed that similar VHF currents flow in both Rs and Ls, you proffered
unplausible arguments to the contrary.

> You realize if the nichrome in the suppressor's winding of wire does not
> significantly lower VHF Q, then everything you attribute to VHF
> oscillation must be a product of vivid imaginations, or directly
> attributed to MY claim that HF Q and mistuning / overdriving are the major
> causes of arcs and sparks in the tank.

I do not realize that resistance wire (nichrome) has no effect on VHF-Q. I
have observed that the VHF dip in amplifier anode circuits is rather
different when silver-plated strap suppressor inductors (Ls) are replaced
with a resistance wire Ls. With silver (and copper), the dip is sharper
and deeper. With the resistance wire, the dip is broader and shallower.
With roughly equal currents flowing in Ls and Rs, why not?
This is nothing new, Tom. Mr. F. E. Handy was aware of this technique 70
years ago.. You can read about it in the 1926 Edition of the *Radio
Amateur's Handbook*. You can read about it in the 10/88, 9/90, 10/90 and
1/94 issues of *QST* magazine. There's an article about calculating values
for VHF parasitic-suppressors in the 3/89 issue.

> Let's make an agreement.

I am reluctant to make an agreement with you, Mr. Rauch.

> If I can not lower Q (using coventional components) the same amount or
> more at VHF without adding as much loss of Q on ten meters as the nichrome
> does, I will concede you have been hawking something of ### great
> technical merit ###. I will endorse your product as a good method of

> parasitic suppression.

An endorsement from someone who dismisses well-established AC circuit analysis , who purports that dipmeters are incapable of finding resonances, would amount to an UNendorsement.

While it is true that the HF tank transforms the 50 ohm load to the anode's load R requirement, this is only the case at the operating frequency. At the anode circuit's VHF parallel-resonance, this is not the case. Parallel resonant circuits exhibit high R---and the higher the Q, the higher the R. . Since V gain is basicly mu multiplied by load R, the amplifier tube's V gain could be high at the anode's VHF resonance---provided that its VHF Q is high. When a typically 1k to 4k ohm termination in placed on the anode by the network analyzer, this is certainly representative of the HF load R. However, the actual load R at the anode's VHF resonance could be hundreds of k-ohms. For example, with a 2k ohm load, VHF gain might be so low that oscillation could not occur. However, with a 200k ohm load, V gain would be substantively higher and VHF oscillation might be sustainable.

That's pretty similar to my original thoughts. I took a look
at some of the Motorola hybrid application notes and decided
on the following:

1. 1nF and 100nF capacitors decoupling the Vcc and Vbb lines
immediately where the module wires are soldered to the pcb.

2. Ferrites on all power lines.

3. 10uf Tantalum bead capacitors at the power feed end of the
line (opposite side to the ferrite beads)

4. Vbb via a MC7809 regulator mounted on the board.

5. Vcc from the main +ve rail.

If you think this should be okay I'll go ahead - the modules
are pretty expensive so I don't want it to go up in smoke !

Hi folks,

Are there any mods available for the Heathkit SB1000 Linear? I am just about to put an original kit together and before I do I'd be interested in alterations ie use on 6m by dropping out say 160m, alternative taps on the pi network coil for 17m and 12m operation without compromising 15m and 10m too much, electronic bias switching etc. Any known hiccups with the linear to be aware of?

Many thanks

Duncan

Hi Mike, if I understand your thread, you can not dip the plate
current (whatever the load setting). If this is so, you are loaded
too heavy (not enough load capacitanc). Check and see if you have a
fixed capacitor in shunt with the output load variable capacitor. That
condenser could be open. With good tubes, properly tuned and loaded
into a load, you should be able to see at least 1000 watts output. In
ssb mode voice PEAKS should be around 300 - 400 ma.

In a 3-500Z, during signal conditions, the instantaneous anode-current normally varies from 0mA to 1200mA during each 360 degree cycle. Are you saying that the anode R is constant over this range of currents?

> You overlooked critical facts. V gain = mu * Rl is untrue in the case of :

Sure, Tom, it's a complicated picture, but voltage gain is basicly mu multiplied by R-Load. In fact, mu is not a constant. At low values of anode I, mu is highest. At high values of anode I, mu is relatively low.

When I use my Millen dipmeter (which is not a grid dip meter/'GDO' since it uses a FET), I do not place an assumed R load on anything because I am looking for a resonance. The guy who placed an assumed R load on the anode is the guy with the sophisticted circuit-analyzer.

> value of anode load resistance for maximum gain at higher frequencies, and
> it is considerably lower than would appear with a 200k load resistance.

A VHF RL of 200k was my mistake. The VHF load presented to the anode is determined by the VHF Q of the anode resonant circuit, which is partly influenced by the Q of the VHF parasitic-oscillation suppressor. I'm guessing that the typical VHF load is a lot closer to 10k ohms. I'll know more when I get the results of some VHF Q measurements. // Maximum power gain and maximum voltage gain are not the same.

> Look closely at the self-contradiction this new Measures theory produces.

> This brings three questions to mind.
>
> 1.) How does the tube draw large amounts of VHF current if the anode is
> driving a high Z parallel resonant circuit at VHF? That is impossible.

IMO, when a VHF oscillation begins, the VHF load R is high, and the VHF voltage gain is high---so little current flows initially. However, if a VHF arc occurs in the anode circuit, the load R picture changes abruptly. The impedance of a metal-vapour arc is quite low---so much VHF current could flow, and apparently does.

snip.

> 3.) How does the VHF energy excite the grid enough to "boil the gold?"

I am unable to explain it. Mr. Foote said that this was the opinion of the 8877's engineers. However, I am convinced their opinion is correct. This is why: I have seen a number of gold-sputtered 8877 grids where no gold appeared to have evaporated from the end of the grid farthest from ground. However, gold had evaporated near the grounded end of the grid. This sort of current distribution can not be explained by HF energy.

I've built a "Patch" antenna for the 1545 Mhz GPS band, and so far it seems to increase the received signal strength a bit, but not to my liking.

Authors of a couple articles on the topic have referenced a "MARS6" op-amp that they've used in this application with some success. I've not been able to cross reference it or find anything close in the catalogs and data books I have.

Anyone out there who can aim me in the right direction?

What, no book?

I don't know what your concern is about the arbitrary 1 amp current limit, as for example, my SB-200 (with brandy new Svetlana finals), which uses two 572-B's at about 2150 vdc fully loaded, draws maybe 575 mA at maximum output. So I would expect a quad to draw twice that. If you are unloading the final to stay under this 1 amp limit, you may tend to increase the chance of arcing, rather than eliminate it. I would just tune for maximum output, at the rated grid current limit for the four tubes, then over-couple a bit, and go. Amps, schmamps, I say. But I would probably do it all at the HV setting, rather than at LV and then flipping the switch. Not good.

Then again, I could be full of crap, or more likely, partially full of crap.

Like that Clipperton? Does it have tuned input? How can you tell (another discussion I'm having)?

Dear friends I have one question and want you to help me. I
own a Icom 706 rig and two sticks for 20 and 40 meters. The
antennas are Valor Pro-am 3/8" conectors and they provide me
very good performance when used with a single magnet mount
on the roof of my 1990 Ford Fiesta car. The problem is that
I can not use it when moving the car because of the poor
catch of me magnet mount. I have tried several times to
mount the aerials in a hatchback mount, but performance and
SWR are very bad indeed. I donnot know how to improve it or
how to use it on the move. The aerials are almost 2 meters
long, half helicoidal half steel stick.
Also will be wellcome any mods, commnets, improvements or
anything about the ICOM 706 rig, how much power can it run,
etc.
Sorry for my English, thanks for your help.

snip

Has anyone built the Ramsey 440 MHz transciever, and used it successfully for 9600 baud packet operation? Did it work as advertised, or are there mods necessary to get it to work? Their catalog says "9600 - no problem". Does that mean "works fine, no problem" or "no problem, not a chance"? Anyone use one of these as the basis for a repeater? Can you use the Tx and Rx side at the same time? I suspect that the synthesizer can only handle one side at a time, but I've never even seen one of these rigs. Anybody?

Thanks,
Ed Burress

From: rdewan@uhura.cc.rochester.edu
Message-ID: <1996Dec9.212216.18305@galileo.cc.rochester.edu>
Source record: 99803

I have a Weller 1001 soldering station that is acting up.
I heats up to about 120f (measured approximately by hand)
and then it cycles off. If I cool the tip by touching it
then it cycles on to about 120f or so.

Any suggestions for fixing this are appreciated.

BTW, this problem occurs regardless of the temp pot setting.

regards,
Raj n2rd

>the anode circuit's VHF parallel-resonance, this is not the case.

You totally missed the point. The operating tube offers a load resistance
to the element even at VHF. That fact was stated several times in several
ways. Contrary to what you may think, the driving and anode impedances of
the tube are not infinite.

>Parallel
>resonant circuits exhibit high R---and the higher the Q, the higher the
R.
>. Since V gain is basicly mu multiplied by load R, the amplifier tube's
V

You overlooked critical facts. V gain = mu * Rl is untrue in the case of :
1.) An amplifier with feedback.
2.) An amplifier with control grid current.
3.) An amplifier with shunt and series impedances.

>When a typically 1k to 4k ohm termination in placed on the anode
>by the network analyzer, this is certainly representative of the HF load
R.
>However, the actual load R at the anode's VHF resonance could be hundreds
>of k-ohms. For example, with a 2k ohm load, VHF gain might be so low
that
>oscillation could not occur.

The load Z is comprised of many things, most of which you have ignored.
The biggest flaw is you have assumed to know the impedance of the anode,
yet you only have a GDO. While the load I used is not ideal, it was
approximately correct for the steady state bias condition of the tube.
Your analysis was correct only if the tube is cut-off and lossless, a
point at which point the tube is not operating anyway. Why investigate the

cut-off impedance condition?

>However, with a 200k ohm load, V gain would
>be substantively higher and VHF oscillation might be sustainable.

I can see you haven't worked with many amplifiers. There is an optimum value of anode load resistance for maximum gain at higher frequencies, and it is considerably lower than would appear with a 200k load resistance. You can see this effect in a hi-fi amplifier, where large grid and anode resistances limit high frequency response.

You are using class A dc or very low frequency AC circuit parameters of a tube with no grid current or feedback at VHF RF.

Look closely at the self-contradiction this new Measures theory produces.

You claimed earlier, both here and in your articles, VHF current gets very large in the tube. You also claimed tank component voltage gets very large from parasitics.

Now you claim the anode has a parallel resonant circuit between the tube and the tank that makes the anode load impedance high. This brings three questions to mind.

1.) How does the tube draw large amounts of VHF current if the anode is driving a high Z parallel resonant circuit at VHF? That is impossible.

2.) How does the VHF energy at the anode make it past the high impedance circuit to the low impedance shunt C of the HF tank? The current now has to pass through a hi-z parallel resonant to reach the tank (that has a very low shunt impedance at VHF) and be able to drive the low Z HF tank to high voltages. That requires a large amount of current, but the series path, according to you, is a high Z path.

3.) How does the VHF energy excite the grid enough to "boil the gold?" You claim the VHF oscillation drives the grid into great current, yet using the mu*Rl gain calculation the presence of any grid current greatly reduces gain, feedback, and the level of any oscillation.

You are arguing against your own theories and methods again.

73 Tom

>RFC.at the open end.

Right, which is why we wouldn't use a grid lead to ground of 30 inches in a GG amp. Duh!

OTOH, a direct 10 millimeter path to ground would first appear as a high Z at 7.5 GHz. With HF power tubes, we can ignore that because transit time effects won't let them be amplifiers up there.

Of course "ground" can be a nebulous thing. It is just something we arbitrarily pick to be a zero potential reference. In a GG amp, it is the grid to chassis connection point by definition. What we are really concerned about is the length of the cathode and plate return paths to that point.

In a well laid out amplifier using a compact power grid tube, the cathode return path can be less than 25 mm (though it is often longer). That's a high Z at 3 GHz. The path from the plate to the chassis/grid connection point is usually much longer, about 200 mm or even more, and that's a high Z at 325 MHz. Capacitive loading can lower that into VHF, and that's what we have to deal with via suppressors.

>Does anyone have any input on the Ten-Tec 2 meter FM Transceiver that you
>assemble from a kit?

It is a good kit. If you want to build a kit radio, this is the one
to buy. But it is a pretty plain radio. If you want the most bang for
the buck, you'll go another way. There are two alternates. You can
retune commercial surplus radios. This gives you a very high performance
radio at a very low cost. Of course it will have even less features
and frills than the Ten-Tec. Or you can buy a Japanese radio. There
are several in approximately the Ten-Tec price range, and they offer
many more features and frills. A very few of them even offer better
performance than the Ten-Tec kit.

>Also, I am wanting to get into packet, and I notice that this rig has a
>1200 baud packet-ready din on the rear. Being in computers, I am use to
>28.8, 56k, etc. Is 1200 baud useable, does packet go any faster?

1200 baud is *barely* usable. It depends on your temperment and what
you want to do. For unattended Email forwarding, it is Ok. But for
many interactive uses it is intolerably slow. Unfortunately, it
represents the lowest common denominator among amateurs, so you'll
find yourself limited in the number of stations you can contact if
you get something faster. It will work through any voice grade FM
radio without modification. Having the jack on the back is a
convienence, but not a necessity. You can just hook a 1200 baud
modem to microphone and speaker connections instead.

Faster packet does exist. As a matter of fact, I was easedropping
on a couple of our 56 kb LAN users this afternoon while they were
exchanging live realtime digital video with CuCme. You can't do fast
packet with a voice grade FM radio anyway, you need a real RF modem
like the GRAPES modem, so you shouldn't let that drive your voice
radio choice.

OTOH, there is 9.6 kb packet. This *can* work through some, a
very few, voice grade radios, and many amateurs try. But most
of the so-called "9600 baud ready" voice radios are *not* in fact
suitable for 9600 baud operation. They have a connector labeled
"9600 baud", and advertising hype claiming they will work, but
they don't, and generally *can't* work properly at 9600 baud.
This is because of the way modulation is introduced into the
synthesizer loop. Again, a dedicated data radio, like the
inexpensive Tekk KS900, is the proper way to go, so don't let

this drive your voice radio choice either.

>means. that virtually guarantees splatter, power overshoot and PA arcing.

Many amateurs tend to treat ALC as if it were a RF speech compressor.
In a sense it is, but it is generally a poor one. It is better to set
the exciter drive to the desired level and leave it that way. With some
radios, you can do that by feeding a fixed voltage to the ALC input.
With others that won't work because of the way they handle the ALC
internally. These radios require modification to reduce drive.

Rather than dissipate a 100 watts in a resistor, it often makes
sense to dissipate a fraction of a watt in the pre-driver of the
rig instead. Adding a small switched attenuator here can allow
you to set output power virtually anywhere you like, and have
confidence it will stay there. If you want speech compression,
a form of distortion, then you can add that too. For myself, I
think linear amplifiers should perform linearly, and not be
used as non-linear distortion generators.

>anode supply.

Rich, you cannot use average ratings directly to determine transient peak performance. If you look at the performance specifications for any tube in *pulse* service, you'll note that the peak pulse power is many times the average sustained power. A transient overshoot is a *pulse*. It represents an unsustainable discharge of stored energy in the tank and power supply. Even quite small tubes can have peak pulse powers in the megawatts. But of course the repetition rate has to be quite low to allow the tube cathode, and the tank and power supply, to recover, so average power remains low.

>can, and you have the quietest oscillator short of crystal control.

In control system theory, this is called a bang-bang servo. Corrections
are periodically pulsed to a storage capacitor feeding the varactor.
The storage capacitor acts as a very long time constant low pass filter.
Since it is only occasionally driven, perturbations in the oscillator's
short term output only occur occasionally as well. It isn't as clean
as a crystal or LC free running oscillator, but it isn't as constantly
noisy as an oscillator under constant proportional control either.
With a basically stable oscillator, you'll only hear a correction
"tick" once every few seconds.

Ham Radio Online is now in its second year of continuous publication on the Internet. With readers in 53 countries around the world, Ham Radio Online is one of the world's most popular amateur radio web sites. Visit us at http://www.hamradio-online.com

We have feature stories added all the time, real-time radio propagation and aurora information, equipment specifications online, a huge library of past articles, current disaster situation reports, commercial products directory and one of the largest directories of Amateur Radio web sites on the net, plus an opinion section and a bulletin board where you can post your own messages.

Right now, wee have stories running on DXpeditions, African shortwave broadcasters planning to switch to digital satellites, Guatamala auctioning off the 70cm ham band to commercial users, news on AMSAT Phase 3D and AO-13's recent death, Global satellite navigation technology and so much more. We've got 20 new stories in the queue right now. Watch for them over the coming month or two.

In spite of our professional appearance, we run Ham Radio Online as a hobby. So please stop by and enjoy. If you have a story or announcement you would like to add, please pay us a visit and drop us some email to vbook@vbook.com.

Thanks and 73,

Source record: 99876

Hello !

I just bought a CW-N filter for my Icom IC-725.
The filter recomended on the manual is the FL-101, but the
one I got is the FL-63 (used on the 735).
The socket to connect the filter are different, but I have already
made an adaptor so it can be pluged in.
The question is WILL THE FL-63 WORK AS THE FL-101 ???
They are both for the same freq and have the same caracteristics
(250Hz/-6dB).
I need to know if I can use the filter or must I get the FL-101 ??

Thanks !

I've used Mitsubishi models from 2M through 27cm with very good success. There really isn't a lot special you have to do to make them work. I would probably decouple with a ferrite bead on the three Vcc lines and use normal bypassing technique out beyond them. There are builtin bypasses on all three lines. Shunting with an additional C is possible but runs the risk of a parallel resonance from the two capacitors and leads, so its probably best to use a bead inbetween.

Be sure to have a good ground at the heatsink. Make sure the module sits flat and that there isn't any anodizing on the sink surface which prevents good RF contact.

I've used three terminal regulators as bias sources and switched them on and off to enable the 9V Vbb bias line.

You should be able to transition to microstrip by placing the bias board right next to the package and under the pins.

I would comment that using "art" type software for schematics is only good if
you don't need to go to the PCB stage. The great power of a CAD program is
that you can create a schematic that generates a netlist. This lets you
verify each connection as you design the PCB. Making it Science not art!
I can't tell you how crazy it makes me to manualy verify each connection
from a tape up vrs the schematic. A program I deal with called Circad works
from start to finish. Schematic to PCB and Gerber files and NC drill list.
Now adays you can send you Gerber files and NC drill info to places like
Alberta Printed Circuits and get double sided boards with plater through holes
for next to nothing. I dumped all my etch tanks and stinky etching chemicals
long ago. I've also got a special deal with Holophase (They make Circad)
for Hams. I did some work on the Autorouter they include and my reward was
to have a version for my fellow hams at less than 1/3rd the cost. Same software
(but from me) Support is only through my little company (Dover - 612-492-3913)
and updates are $50. Cost of the program is $295 - Shipped. EMail me if your
interested or check out the new WEB page www.holophase.com
73 and good luck on your projects!

Gary's idea is a good one, it satisfies the need to limit the gain when power is reduced.

There should be enough head room above the attenuator's power setting to allow good linearity, that's why I prefer external fixed ALC voltage to any attenuator if possible. Fixed external ALC reduces the chance of saturation in a low level stage, if that method can be used.

This is also why the linear amplifier driving requirement should as close to the exciters rated power as possible. Using a 150 watt capable PA with a 50 watt drive PA (or tuning your PA with 50 watts) is asking for trouble with arcs, sparks, and splatter.

Hi Gary,

Rich's examples were overexaggerated. He made the L/W ratio of the lead 5 in one case and 2 in another. When the L/W ratio is made lower and lower, the lead behaves more and more like a continuation of the groundplane. Z is relatively low regardless of lead length.

We always need to consider the L/D(eff) ratio, and the D to wavelength ratio.

>1 Amp plate current being drawn. The high voltage is about 1500
>volts. Pretty bad efficiency at about 47%.

That's not so bad for that layout and those tubes. Especially since you probably have no idea how accurate the meters are in the Dentron and the wattmeter.

Remember the tank is jammed into a small case in that amplifier, and 572B's are not the most efficient tubes. With an excellent layout and 572B's you will only get 60% or so efficiency. You may, if the meters are correct, be near the dissipation rating of the tubes. But remember the dissipation of the anode is given in time average power over a period of perhaps 30 seconds.

>If I push it harder, plate
>current goes beyond 1 amp, and arcing begins (arced once anyway).
>This is in "low" power mode, 1500 volts, if I kick it to high power or

>in. I cannot drive it harder that say 50 watts or so without plate
current
>going beyond 1 amp input. I can't even back it off with the load or
>tune. Is this normal for this amp?

Never underload a grounded grid PA, always tune for maximum output power and not by watching plate current. If you have to watch current, watch grid current and keep it below 50 mA per 572. Excess grid current will destroy a tube fast, excessive plate current (if you don't actually overheat the anode) is not a problem in a throated tungsten cathode tube. Tube emission life is more a matter of filament hours and temperature than current.

>Will I blow it if I run it at 1 amp
>plate current in?

No one can answer that in absolute terms. The plate current rating is .25 amperes per tube for continious uninterupted operation, so it's doubtful you'll hurt the tubes in amateur service. Plus as I said, with thoriated tunsten tubes operation at current saturation (which is nearly .8 amperes per tube!) does little long term damage as long as the elements in the tube are not overheated. Emission life is a function of hours and filament

temperature rather than emission current.

The power supply is another story. It is impossible to accurately predict life of components that are that old when they are stressed.

The Dentron is unstable on 21 and 28 MHz, and oscillates on those bands under some tuning and load conditions. Other than that, the amp should be fairly durable IF you load the amp heavy enough. The only chronic problems are Dentron's use of carbon bleeder resistors across the caps and some small low voltage resistors across the diodes. Both of these design errors should be corrected.

The combination of 572Bs require neutralizqation on 21 and 28 MHz, and Dentron did not do that. It would be tough to add a neutralizing circuit in that case. You may find lowering circuit Q on 21 and 28 MHz helpful, but that will never be a good PA on those bands for many reasons.

Until you confirm the metering is correct, very little can be answered about efficiency.
Do NOT use the loading control to reduce plate current. That mistake can cost you tubes, bandswitch, or other component failure. Leave the loading heavy, and reduce the exciter power, or better yet add a series resistor pad between the tubes and the driver to reduce drive power.

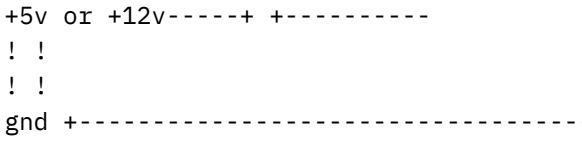
3816. I need a little help in designing a sequencer...

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-10 00:00:00 UTC
From: morris@cogent.net
Message-ID: <morris.990.00924DEA@cogent.net>
Source record: 99806

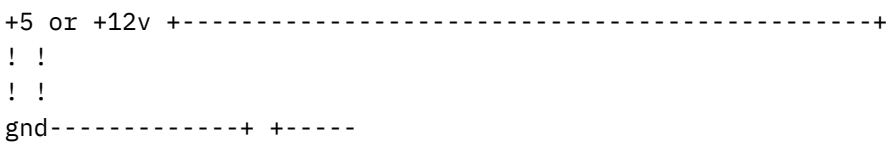
I'm trying to come up with a method of controlling the power to some equipment.
I've experimented with capacitors and relays, but can't come up with something
that is as dependable at 35 farenheit as in 120 farenheit (i.e. winter
overnight to summer mid-day) - it's for a mobile application.
I could use a 555 driving 3 "D" type flip flops, or some firmware in a
PIC processor, but I was thinking that there has to be a simple way that
I'm overlooking.... Maybe I've been mangling computer code too long...

Heres the requirements - I suggest that you use a monospaced font
(like Courier) to view this timing diagram. The timing resolution that
I need is about 1/4 to 1/2 second between signal rises and drops (it's
not that critical), and current handling of under 500ma per output. I
have circuitry that will handle everything but the actual sequencing.

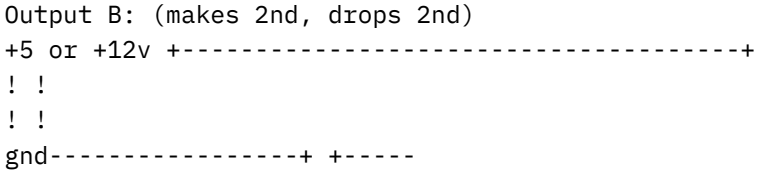
The control signal:



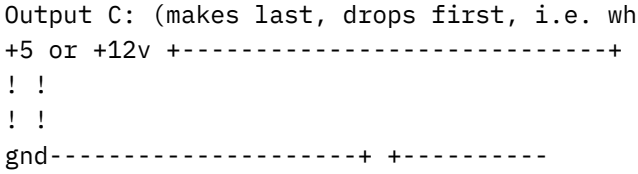
Output A: (makes first (i.e. immediately), drops last)



Output B: (makes 2nd, drops 2nd)



Output C: (makes last, drops first, i.e. when the control signal goes inactive)



Anyway, any help will be VERY much appreciated.

One good way to smoke them is to exceed their maximum drive power
limit. The limit is always well above what is needed for maximum
output, but if your driver stage has excess power output be careful.

>that they've used in this application with some success. I've not been
>able to cross reference it or find anything close in the catalogs and data
>books I have.

The MAR-6 is an RF Amplifier sold by Mini-Circuits.
It's specs are 9dB gain, DC-2Ghz, with a 3dB Noise Figure.
A MAR-6 is less than a dollar, in qty of 30.
For 30 bucks, you could get a lot of projects done...

Mini-Circuits can direct you to a distributor: (718) 934-4500

In article <measures-ya023180000912961112450001@news.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

>In a 3-500Z, during signal conditions, the instantaneous anode-current
>normally varies from 0mA to 1200mA during each 360 degree cycle. Are you
>saying that the anode R is constant over this range of currents?

No, I'm just pointing out your measurement technique is the worst of all,
because it is taken when the tube is cut off, a condition when the tube
can never oscillate. It is much better to test under average or typical
quiescent current conditions of the tube in conduction than to test in a
condition when it is impossible for oscillation.

>> The load Z is comprised of many things, most of which you have ignored.
>> The biggest flaw is you have assumed to know the impedance of the
anode,
>> yet you only have a GDO.
>
>When I use my Millen dipmeter (which is not a grid dip meter/'GDO' since
it
>uses a FET), I do not place an assumed R load on anything because I am
>looking for a resonance. The guy who placed an assumed R load on the
>anode is the guy with the sophisticted circuit-analyzer.

The very act of coupling the dipmeter to the circuit loads the circuit
with an uncontrolled and unknown load. Not only that, with such a crude
instrument you have no idea what you are measuring in a complex system.
Dip meters are fine for measuring the resonant frequency of a simple
parallel tuned circuit, but useless for analyzing complex impedances.

My point stands, you have no idea what you are measuring...except the
point where maximum energy is extracted from the dipmeter's tank.

>A VHF RL of 200k was my mistake. The VHF load presented to the anode is
>determined by the VHF Q of the anode resonant circuit, which is partly
>influenced by the Q of the VHF parasitic-oscillation suppressor. I'm
>guessing that the typical VHF load is a lot closer to 10k ohms.

Is that as good a "guess" as the guesses made about parasitics melting
glass in Chinese tubes, photons destroying tubes that are on standby, 500
watt dissipation 8877 grids, saturation of 3-500Z anode current with 150
watts of drive, and the overshoot in the tank when the PA is improperly
coupled to the load? Do you think it's a good idea to guess about things,
and then claim they are facts?

> IMO, when a VHF oscillation begins, the VHF load R is high, and the VHF
>voltage gain is high---so little current flows initially. However, if a

>VHF arc occurs in the anode circuit, the load R picture changes
abruptly.
>The impedance of a metal-vapour arc is quite low---so much VHF current
>could flow, and apparently does.

The metal vapour arc you allude to is still on the wrong side of the parallel resonant circuit, in the tank area. We already know that area has a low VHF impedance, making the tank impedance lower won't change a thing. Besides, the arc can never start from VHF signals because we still have the VHF anti-resonant circuit between the anode and the tank, and that is according to you!

In order for the tube current to be high, the arc has to be on the driven side of the parallel tuned circuit. In order for the tank current or voltage to be high, the arc has to be across the parallel resonant circuit.

You claim we have this:

tube anode>---high Z parallel resonance------low Z tank-----ground

Please explain how the tube current can be high, and the tank voltage and current high with this type of connection. Do you wish to amend your claim?

>> 3.) How does the VHF energy excite the grid enough to "boil the gold?"

>I am unable to explain it.

So you really don't know WHY it happens, you just "know it does". OK.

>Mr. Foote said that this was the opinion of the
>8877's engineers.

You claimed earlier Foote told you this verbally, in a telephone conversation. No one at Eimac has heard of this, except in one UHF triode.. as I recall that tube was a 3CX10000U7. Reid Brandon, John Button, Dave Chazen, Buzz Miklos, Bill Orr, Jim Aurand, Dave Peterson, and others all dispute this claim.

Bill Foote is retired now, but his job was to answer customer letters in the returned tubes section. He was not a design engineer, or even an engineering to customer interface person like Brandon is.

I don't fault you for hearing things the way you want to hear them, we all tend to hear what we want to hear. I'm absolutely sure that's what you "heard" during the verbal exchange with the fellow not even in the correct plant or job for direct access to the information. It is comforting to hear you admit you have no idea WHY the problem occurs.

>However, I am convinced their opinion is correct. This
>is why: I have seen a number of gold-sputtered 8877 grids where no gold
>appeared to have evaporated from the end of the grid farthest from
ground.

>However, gold had evaporated near the grounded end of the grid. This sort
>of current distribution can not be explained by HF energy.

How large was the number of tubes in you sample group?

Eimac was curious about your claim. They wonder what the tube code dates were, and how many tubes you actually looked at. They asked if you still have a tube to send to them.

Their records indicate the majority of tubes failing lose gold in the upper end of the grid structure, except for a series of tube failures caused by a heat dam problem at the base of the grid.

Are you sure the damage you saw was not related to the heat dam problem in that area of the tube? The heat dam (coated with a gettering agent) contaminated the grid and caused the gold nearest the heat dam to fail. At various periods of time, 8877's had this problem.

ITU'S HOLIDAY SALE!
See our web page for more details
http://www.itutech.com

If you've ever wanted to get started with the Microchip PIC family of microcontrollers then now is the time! Our SPECIAL HOLIDAY packages are the perfect way to GET PIC'n! We've bundled our popular programmers with Square One Electronics' Easy PIC'n Book and an electrically erasable PIC16C84 microcontroller to get you started in the wonderful world of PIC microcontrollers today.

****
Package #1

* PIC-1a Programmer (reg. $39 kit, reg. $59 Assembled/Tested)
* Easy PIC'n microcontroller book (reg. $29.95)
* PIC16C84 microcontroller (reg. $8)

GET PIC'n Pack #1 - All of the above for only $59 Kit, $79 Assembled!

****
Package #2

* Warp-3 Programmer (reg. $129 Assembled/Tested)
* Easy PIC'n microcontroller book (reg. $29.95)
* PIC16C84 microcontroller (reg. $8)

GET PIC'n Pack #2 - All of the above for only $149!

****
PIC-n-GO Package

* PIC-1a programmer kit (reg. $39)
* PIC16C84 microcontroller (reg. $8)

PIC-n-GO Package - All of the above for $39 kit, $59 Assembled!

****
Add our advanced development environment, CESSIM, to any
of the above packages for the special holiday price of only
$49 (reg. $99)!
****

Please see our web page for more product information,
http://www.itutech.com

SPECIAL EXPIRES 12/31/96, SO ORDER TODAY!

ORDERING INFO

We accept Visa, MasterCard and American Express credit cards, personal checks and money orders, or COD orders (add $5). Please add $5 shipping inside the US, $10 for airmail shipping outside the US. All products are sent UPS ground unless otherwise specified.

You may order via phone, fax, mail or on-line using our new SSL SECURE Web Order Form. Please see our web page for details.

Jay Craswell <73016.27@CompuServe.COM> shared these priceless pearls of wisdom:

->Circad is $995 (Unless your a Ham, Ham price=$295) Drop me an E-Mail if
->your interested. Or check out the WEB site www.holophase.com

I downloaded the "try me" version of Circad and I'm having some trouble getting started. Like any wonderful program, it is only wonderful if you can use it. There isn't any printable documentation OR sample files to load and play with.

Also, there is supposedly an "educational" version of this program that is available to electronics teachers. How do we find out about this version?

I guess it boils down to this:

1. The sample program is crippled on the size of file you can save, but nowhere is the crippled size documented. What is the cripple limit?

2. What are the limitations on the ham and teacher versions of the software? Pins? File size?

3. What are the limitations on the full software?

4. Where can we get decent printed instructions and/or sample files?

==========

In Mr. Rauch's post of 28 Nov. he said:

> A second factor enters the equation, and this is the critical area. Adding nichrome to the primary HF path does almost NOTHING to system Q. I have no idea what guage wire you use, but let's look at some typical suppressors when 5 ohms of ESR is added to the inductor Here are the numbers:

With your suggested values of 70 nH and 50 ohms at 100 MHz.
Q = 1.14 (par equiv values (p eq) are 50r and 70 nH
with 5 ohm esr from nichrome.
Q = 1.0 (p eq) = 44.34r and 70.9 nH

With 70 nH and 100 ohms:
Q = 2.3
with 5 ohm esr nichrome
Q = 1.8 (p eq) = 79.7 r and 70.9 nH

With 150 nH and 50 ohms:
Q = 0.53
with 5 ohms esr nichrome
Q = .5 (p eq) 48.6r and 150.4 nH
snip

==========

The First Problem : (note m.s=milli-siemens)
.....for the series of 70nH L and 5 ohms of R, at 100MHz, I calculated that XL=44 ohms. For 5 ohms of R and 44 ohms of XL, Z = 44.3 ohms at an angle of +83.5 degrees. To convert this to its parallel equivalent: Y=-1/Z = 1/44.3 ohms, or 22.6 m.s at an angle of -83.5 degrees. BL = sine of -83.5 degrees*22.6 m.s = 22.4 m.s. Using X=1/B = 44.64 ohms of XL. G = cosine of -83.5 degrees * 22.6 m.s = 2.55m/s. Using R=1/G, R=44.2 ohms. Using Wes' suggestion, 44.2 ohms in parallel with 50 ohms =23.5 ohms. Q=R/X = 23.5/44.64 = 0.52.

It looks like the relatively small amount of ESR in the nichrome Ls made the VHF parasitic-oscillation suppressor's VHF-Q decrease from 1.14 to 0.54.

Tom: please show us how you arrived at a Q of 1.0.
I certainly would not want to continue with the second and third examples you proffered if there is an error in my method of solution.

>the signal can be cleaned up? - Mike
>

I'm not sure what kind of noise you are seeing, but here are some
general things I've found about scope triggering on video:

The best O-scopes to use for video waveforms tend to be the Asian
imports like Hitachi, Anritsu and some of the others that appear
under domestic brand names like Sencore, B&K etc. What you will
notice about these is that they have video mode triggering
built in. These trigger modes are usually marked TV-H or TV-V
for horizontal or vertical interval triggering. These units
appear to be designed with TV service in mind and are very good
even with a lot of noise on the waveform. The drawback is that
these scopes are not the fastest in the world and don't compare
well to the better Tek scopes for high frequency measurement.

If you have a scope that does not have TV mode triggering, you
can build your own using an LM1881 (see National's web page).
The sync detected outputs from the 1881 is clean and can be used
to provide external trigger to your scope. You just need to
make sure that the video level at the input to the LM1881 is
within the device limits. If your scope has a buffered output
from one of its probe channels, this is generally the best place
to sniff out some video to drive the 1881.

Good Luck,

Steve Muther WF6R

MAR MMICs (Monolithic Microwave ICs) are made by Mini-Circuits. Their
US number is (718) 934-4500. They are quite inexpensive, and very easy to
use, having 50R input and output impedances.

> the signal can be cleaned up? - Mike

If you're triggering your scope at line rate I'd guess you're seeing the
broads (UK-speak for vertical sync) running through at field rate.
These would be fairly faint as they're not there all the time :-)
As it's of very low frequency, compared to the horiz sync, it shouldn't
be a problem...
However you might find the output from your VCR is pretty unstable.
What device are you trying to trigger?

Tom,

Concerning the data you have been posting..... were you measuring this stuff by connecting your instruments to a commercially made amp, just as I might buy off the shelf? Or, were you using a test circuit strictly designed to determine the operating characteristics of a tube?

Thanks.

Tom KJ5IE

3837. Capacitance triggered iambic key

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-10 00:00:00 UTC
From: rdtalbert@aol.com
Message-ID: <19961210204900.PAA27727@ladder01.news.aol.com>
Source record: 99827

Several years ago I built (from a magazine article, as I recall) an iambic hand key that was triggered by body capacitance. This was the slickest, most simple and easy to operate key I have ever used.

Unfortunately, my key was demolished (almost beyond recognition) when I moved several years ago. Now that I am becoming active in radio again, I would like to build another.

The circuit seems to consist of 3 unidentifiable transistors (small d-shaped plastic case type), 2 small electrolitic caps, and maybe 3 or 4 resistors.

Could anyone help me out with the schematic and parts list for this little jewel? I don't have an extensive library of past issues of amateur radio magazines but reference to a past article would certainly be better than nothing.

Thanks and 73

Roy K9ER

3838. RF Mirror for 2.4 GHz

Bad idea... Unless the line is EXTREMELY low loss, you will lose most of your power anyway. A vastly better idea is to match the *antenna* to the line, by fussing with the gamma match, element lengths, or whatever. Then the SWR on the line is low, and there's no need to have a tuner at all. The reason people use tuners at HF is that there, coax, and especially open wire line, do have low loss, and so can run at high SWR without causing excessive losses. Not so up at VHF or higher.

Source record: 99832

Does anyone have an instruction sheet for a Stancor A-3893 (1960 vintage) or other "Poly-Pedance" modulation transformer of the A-389x series. Need the taps and jumper connection chart to match impedances.

These transformers were for a multitude of impedances as reported in their catalogs and were used in the ARRL Handbook for one or more modulators around 1960-1965. But the construction articles never specifically identified the taps to be used, rather refered the user to the instruction sheet packed with transformers to determine which taps are shorted and which ones are used for the plate connections. The operating current & voltage determined the impedance and tap adjustments were required to get the ratios right.

To be sure I get your response if you can help, please copy to:

I have a Regency Micro Com PH-251A handheld 2m rig
I'd like to trade. It's only a single channel, and not
even on a ham channel! Currently crystalled for
151.805, xmt and rcv. Has slots in PCB for a number of
additional xtals if you felt like putting them in.
This is the standard Regency handheld of old.

With leather case, and Wilson BC-2C charger base. NiCad
in good shape, radio works very well. With 'duckie' antenna.
Tuned it in on my scanner and it sounds great. 1 watt or
5 watts switchable. External mike/spkr jack in top. Very
good physical and electrical shape

Just needs xmt and rcv rocks for a repeater or simplex pair.

What do I want? $30 plus shipping :(or homebrew parts.

Here's what I'm after:

Vernier dials - the kind you can put a label behind
like the old Johnson series

3-section 1100pf Variable caps

Stripped SB-xxx Heathkit chassis (no parts) - want for
homebrew project

SB-430 Station Console (thingy with the clock, timer, and SWR meter)

500-0-500v 100ma range power transformers - anything close

Coil stock of any airwound flavor

Little unfinished RF / Ham projects that got started and never
finished that have nifty parts inside

Any combinations of the above.

You get the picture....I do alot of homebrewing these days, and my junk box is
as empty as my wallet!

Email to: Dave gekko95@ix.netcom.com

(To those who know me, yes I was gekko@nwlink.com - changed ISP's)

CirCad software -$995.00

This huge support factor was created by the manufacturer to justify the $995 cost I quess. The support was equal to more that $700 of the cost of the program. ...more that $700? You are getting it for less that $295? Right? Per program I should say. Right again? Where could I find an organization that spends 70% of its income from a product to pay for support. That only leaves 30% for rent, utilites, return on R&D...you know what I mean.

Not my concern really just curious but will you explain this lack of support the ham version provides?

Carl

Since you chose not to answer my question let me say:

I have tried CirCad.
The shareware version I tried had crude menus in the manner that a beginner
would make. As if there was no attempt to take the look of the system beyond essential stuff that was available 10 or more years ago. I would think
a program that costly would upgrade to a stylish version like the rest have.

YOU are correct. No support.

The documentation available was really no documentation compared to any other
CAD programs.

Many other CAD programs, shareware that is, and one in particular- DraftCHoice -
makes CirCad look childish.

Hell, Easytrax, can be made to draw schematics, does all the CNC Gerber stuff and it is freeeeeeeeeeee.

If Harvard Garphics 3.0 for DOS would allow .025 inch snap spacing on 8.5 x 11, I wouldn't need anything else. Not even AutoCad.

CirCad, the version I tried, has a value of less than $50. The best version
of DraftChoice is $99. There are many better deals.

Schematic capture? Can't draw the schematic if you can't understand the program.Net list? Bus? Come onnnn.

Carl

In one word, DON'T.

In a few more words: match the impedance correctly at the antenna itself
and operate the feedline at low VSWR to reduce losses. If your antenna
is not matched correctly, it would be bad engineering to build an ATU to
hide the problem - fix the antenna.

IMO, the magnetic characteristic is probably a factor at VHF. By adding a small amount of iron to the basic nickle-chromium 4 to 1 ratio, the hysterisis-loss increases noticably at 50MHz. It will be interesting to see what happens above this frequency on your Boonton 250, Wes.
Another issue is that there are two, different, anode VHF resonant frequencies whenever a VHF parasitic suppressor is used. The higher resonant frequency is through the suppressor resistor, Rs (the lowest L path through the suppressor). The lower resonant frequency is through the more-inductive suppressor inductor, Ls. (Note: Rs and Ls act independantly because the magnetic field from Ls is at a right angle to the magnetic field from Rs, Thus, a stagger-tuning effect is produced.)

A nichrome Ls does increase HF loss by roughly one percent on the 28MHz band. Unsurprisingly, nichrome does exhibit heating during operation at 28MHz. I would be concerned if this were NOT the case.
About 30 years ago, an old timer told me that he built a ten meter antenna with stainless steel screws, and that during operation the stainless steel screws became so hot they melted the plexiglass insulators they were screwed to. (Most types of stainless steel are a mix of nickle, chromium, and iron.)

Subject: Frontier Electric Digital 500.

Hello.

I have an old Frontier Electric Co. Digital 500. It has digital display,
using old tubes for the display. The freq. readout is not working, I get
digits on the display, but they are not correct. It's displaying the right
band, but not the right freq.

Another problem with the rig is that it does only deliver a few watts on the
10 meter band.

All suggestions are welcome!

Help I need a Relay !!! I own this older 10 meter/6 meter amplifier
(AfterBurner Model# 403) and it has been in the closet for a few years
so I
took it apart and thought I should clean the relay (it looked kinda
dirty)
Well, after the file treatment things don't seem to be as flat as they
should and now the realy shoots sparks when you key up. So know I went
on
this search in the net and can't find nothing about a Relay. I even
check
all the parts catalogs I have and nobody has a simple Relay. Can
Anybody out
there help me find the right parts people? If so please help me I need
a
Relay and I need a new parts catalog Thanx :)

IMO, the magnetic characteristic is probably a factor at VHF. By adding a
small amount of iron to the basic nickle-chromium 4 to 1 ratio, the
hysterisis-loss increases noticably at 50MHz. It will be interesting to
see what happens above this frequency on your Boonton 250, Wes.
Another issue is that there are two, different, anode VHF resonant
frequencies whenever a VHF parasitic suppressor is used. The higher
resonant frequency is through the suppressor resistor, Rs (the lowest L
path through the suppressor). The lower resonant frequency is through the
more-inductive suppressor inductor, Ls. (Note: Rs and Ls act independantly
because the magnetic field from Ls is at a right angle to the magnetic
field from Rs, Thus, a stagger-tuning effect is produced.)

From: gekko95@ix.netcom.com (Dave)
Subject: Regency Handheld 2m for Trade for homebrew parts

I have a Regency Micro Com PH-251A handheld 2m rig
I'd like to trade. It's only a single channel, and not
even on a ham channel! Currently crystalled for
151.805, xmt and rcv. Has slots in PCB for a number of
additional xtals if you felt like putting them in.
This is the standard Regency handheld of old.

With leather case, and Wilson BC-2C charger base. NiCad
in good shape, radio works very well. With 'duckie' antenna.
Tuned it in on my scanner and it sounds great. 1 watt or
5 watts switchable. External mike/spkr jack in top. Very
good physical and electrical shape

Just needs xmt and rcv rocks for a repeater or simplex pair.

What do I want? $30 plus shipping :(or homebrew parts.

Here's what I'm after:

Vernier dials - the kind you can put a label behind
like the old Johnson series

3-section 1100pf Variable caps

Stripped SB-xxx Heathkit chassis (no parts) - want for
homebrew project

SB-430 Station Console (thingy with the clock, timer, and SWR meter)

500-0-500v 100ma range power transformers - anything close

Coil stock of any airwound flavor

Little unfinished RF / Ham projects that got started and never
finished that have nifty parts inside

Any combinations of the above.

You get the picture....I do alot of homebrewing these days, and my junk box is
as empty as my wallet!

Subject: Schematic Drawing Software For Ham Use?

Since you chose not to answer my question let me say:

I have tried CirCad.
The shareware version I tried had crude menus in the manner that a
beginner
would make. As if there was no attempt to take the look of the system
beyond essential stuff that was available 10 or more years ago. I would
think
a program that costly would upgrade to a stylish version like the rest
have.

YOU are correct. No support.

The documentation available was really no documentation compared to any
other
CAD programs.

Many other CAD programs, shareware that is, and one in particular-
DraftCHoice -
makes CirCad look childish.

Hell, Easytrax, can be made to draw schematics, does all the CNC Gerber
stuff and it is freeeeeeeeeeee.

If Harvard Garphics 3.0 for DOS would allow .025 inch snap spacing on 8.5
x 11, I wouldn't need anything else. Not even AutoCad.

CirCad, the version I tried, has a value of less than $50. The best
version
of DraftChoice is $99. There are many better deals.

Schematic capture? Can't draw the schematic if you can't understand the
program.Net list? Bus? Come onnnn.

Carl

>
>
CirCad software -$995.00

This huge support factor was created by the manufacturer to justify the $995 cost I quess. The support was equal to more that $700 of the cost of the program. ...more that $700? You are getting it for less that $295? Right? Per program I should say. Right again? Where could I find an organization that spends 70% of its income from a product to pay for support. That only leaves 30% for rent, utilites, return on R&D...you know what I mean.

Not my concern really just curious but will you explain this lack of support the ham version provides?

Carl

Subject: Stancor Poly-Pedance Mod Xfmr taps

Does anyone have an instruction sheet for a Stancor A-3893 (1960 vintage) or other "Poly-Pedance" modulation transformer of the A-389x series. Need the taps and jumper connection chart to match impedances.

These transformers were for a multitude of impedances as reported in their catalogs and were used in the ARRL Handbook for one or more modulators around 1960-1965. But the construction articles never specifically identified the taps to be used, rather refered the user to the instruction sheet packed with transformers to determine which taps are shorted and which ones are used for the plate connections. The operating current & voltage determined the impedance and tap adjustments were required to get the ratios right.

To be sure I get your response if you can help, please copy to:

Hi,
I have a dumb question I hope someone will help me with. I have some
coax connectors I bought to use on a homebrew antenna. I don't know
now if they are 50 ohm or 75 ohm impedence. (I didn't realize it when
I bought them and they aren't marked.) Is there an easy way to tell?
Would 50 ohm connectors have some physical telling difference or can
I measure them with me ohm meter to tell?

Thanks for your help.

>handle one side at a time, but I've never even seen one of these rigs.
>Anybody?

I haven't built the 440 rig, but I did build the 2m rig. The modulation is just summed into the PLL error loop, and if you've been following the 9600 baud threads, you know that's not going to work correctly.

The radio sweeps the VCO to the various receive and transmit offsets by mixing offset reference crystal oscillators with a sample of the VCO in the PLL mixer and feeding that to the PLL chip to generate the loop error voltage to steer the VCO to the proper frequency. You can't use it duplex or split it.

The 2m radio had a *number* of design flaws (I can't claim the inability to do 9600 properly is a design flaw since most other synthesized radios share it, and it doesn't affect ordinary voice use). But for example, it will transmit with the PLL out of lock, a definite no-no. And receive sensitivity was much worse than specified unless modified from the way the instructions tell you to build it. And the PA would go spurious if you tuned it according to the instructions in the manual (you can tune it clean with the aid of a spectrum analyzer, though you might have to settle for about 3 watts out). There were a number of fixes to its various problems which were posted here when it first came out.

I understand that the design has been revised since the first release. I can't say if any or all of the problems noted in the first units

have been resolved because I haven't seen one of the new units. But unless they have been, you don't want this radio except as a learning experience on how *not* to design a radio. There were also problems with component quality. The first radios were sent out with reference crystals which would not net onto frequency. You had to modify the reference oscillators to get them on frequency. Now some of this may be attributed to teething problems of a new product, but most of it is just typical Ramsey.

If you want a transmitter and receiver you can build from kits which will work for 9600 baud, buy the Hamtronics kits. Their quality isn't wonderful either, but at least the design is sound, and they will usually work as advertised after a bit of debugging.

Gary

I'm no expert, and I'm not so sure if connectors are actually designed
to have a certain impeadance. I've seen BNC connectors that were
designed for 50 ohm cable and 75 ohm cable, The end of the cable is
the same. Unless you're doing microwave stuff, it probally doesn't
matter. I am sure of one thing, though, you're not going
to measure the impeadnace with an ohm meter!

=
>cosine of -83.5 degrees * 22.6 m.s = 2.55m/s. Using R=1/G, R=44.2 ohms.

Nope. The parallel inductor equivilent is really 43.98 ohms in parallel
with 386.89 ohms. You need to check your math at the G=cos -83.5*22.6ms =
2.55ms area

Let me do it in decimals instead of confusing milli's this and thats.
Using your numbers as the starting point cos -83.5 is .1132032138 multiply
that times .0226 is .0025584 s. That is about 2.55 m/S. The 1/X of that
number is 390.87 ohms, not 44.2 ohms.

I have no idea where your answer of 1 / 2.55 m/s = 44.2 ohms came from,
since 1/ 2.55 m/s is 392.2 ohms.

So the correct par R answer is 390.87 ohms using your figures (it is
really 386.89, but close enough).

>Using Wes' suggestion, 44.2 ohms in parallel with 50 ohms =23.5 ohms.
>Q=R/X = 23.5/44.64 = 0.52.

Woops again Rich, there must have been a parasitic oscillation in your
calculator, hi.

1/R = 1/50 plus 1/390.87 = 44.329 ohms 44.329 / 44.64 = .993

so Q = .993

By your method Q=.993 with nichrome, not a big drop from 1.14 with a
LOSSLESS suppressor inductor. This is of course different than my posted
value from rounding.

>It looks like the relatively small amount of ESR in the nichrome Ls made
>the VHF parasitic-oscillation suppressor's VHF-Q decrease from 1.14 to
>0.54.

Even if I approximate it a 5 ohm series resistance change from a 50 ohm
suppressor is only 10%. 10% of 1.14 is .114. 1.14 minus .114 is about
1.026. The equiv series inductance also changes slightly so the Q change
will be a little more than that. With my toes and fingers and common sense
I get Q about 1 with the added resistance.

Adding nichrome lowers the HF Q, slightly reducing effects of excessive drive, exciter transcients, and improper tuning. It does NOTHING for VHF stability.

3868. Re: Coax connectors impedence

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-11 00:00:00 UTC
From: Larry Robison <robison@amnorth.com>
Message-ID: <32AF3100.6DFE@amnorth.com>
Source record: 99711

Hi Jeanne:

Connector impedance isn't as confusing as it may seems. The only connectors that are true 50 ohm connectors are "N" and "BNC" connectors. The thing that establishes them as constant impedance connectors is the dimensions of the center conductor pins and the interior dimension of the shell. As in a piece of coax this is the primary thing that determines impedance. The impedance of the connector is really only important in feedlines that are used on frequencies above 30 Mhz. It used to be that only the purists were concerned with 50 ohm connectors because they were always somewhat more difficult to install and were more expensive than their counterpart the PL259.

The PL259 is the old standard for most amateur work because they were readily available, cheap, and fairly easy to install. They will handle the power that most amateur equipment produces, all the way up to a couple of kilowatts without too much trouble. Since their design is not such that they qualify for being a "constant impedance connector" they are used in either 75 ohm cable or 50 ohm cable with equal success.

The PL259 adapters that state that they are for RG58 cable or RG59 cable has nothing to do with impedance. It more has to do with how snugly they fit around the cable, thus preventing physical movement from destroying the integrity of the connection.

I hope this helps.

>for this processor line?
>
OK, I've been using the PIC for quite awhile now, and at work we got a
Picstart 16B-1 I think it is. It does the 16C5x, 16C7x, and 16C8x series.
We paid $200 for it, but they included 4 samples and gave us *lots* of
literature. A few months ago, I picked up a Picstart Plus at one of their
seminars. It was $150, but it does all chips up to 40 pins. Both plug into
the PC via a serial port.

As yo your other question- you can get 8-pin PICs! These have internal
4Mhz oscillators, or can use an external one. You can have up to 6 I/O
lines, but less if you use an external osc. This chip has to rate high on the
'coolness' scale, IMHO. The only problem with it is it's only in OTP, tho
they're going to try and put it in like an 18-pin windowed DIP, according to the
guy I talked to at the seminar. They also have a 64-pin PIC that can control an LCD
display or you can configure it up for *alot* of I/Os, tho I cannot remember how
many.

As to the software, you can get it free from Microchip, and it's pretty darned
good. You can also get things like a 'C' compiler, but I think for a chip with
512 words of space that's way over-kill. (IMHO) PIC ASM isn't too hard to learn-
it's just diffrent. I was saying 'oh, I can do that?' for awhile when I was
programming it. :-)

Also, I find Digi-key's prices to be kinda high for some of the parts, but where
else can you get one of 'em at a shot?

I believe, that the numbering system stated probably is AWG (American Wire Guage).

There is an approximate formula for comverting these numbers to diameter, but I don't have it at hand.

For the guages you mention, the following might help you:

AWG 28 .0321 cm
AWG 26 .0405 cm
AWG 24 .0511 cm
AWG 22 .0644 cm
AWG 20 .0812 cm

There are also British (NBS) guages which are slightly larger for the same guage. I don't believe that for your application, the size will be too critical. If you need other sizes, email and I can send them to you.

Regards, Wes Stewart - N7WS

3874. Help requested in receiving 92 KHz on FM radio

Hello

I recently bought a radio to listen to an ethnic radio broadcast
in the NYC area. The broadcast is at 92KHz freq.

The radio is a regular AM/FM radio converted to receive this freq. on the
FM dial around the 92 Mhz mark.

I wonder if anyone can tell me how this can be done, hopefully inexpensivly.
The reason I want to do it myself is to have more radios of this type
without paying a lot of money for (2 times) for each radio.

Thanks in advance.

: built in. These trigger modes are usually marked TV-H or TV-V
: for horizontal or vertical interval triggering. These units
: appear to be designed with TV service in mind and are very good
: even with a lot of noise on the waveform. The drawback is that
: these scopes are not the fastest in the world and don't compare
: well to the better Tek scopes for high frequency measurement.

Gee, what's wrong with a Tek scope?? Mine (a T932) has TV triggering
modes. And my HP54542A at work also has TV triggering modes (selectable
among NTSC and PAL and user defined rates).

: If you have a scope that does not have TV mode triggering, you
: can build your own using an LM1881 (see National's web page).

Good advice. You can even add a counter to the LM1881 (or LM1882--
more modern. I think National is discouraging use of the LM1881 now.)
which counts H-sync and is reset by V-sync, to trigger on a particular
line in each field (or even each frame). Not a bad accessory to have
for your scope if you do much video work.

Hello....
You didn't mention which type of connector you have, but... In general
the previous post about BNC and type N is true. Ther ARE other 50 ohm
connectors, but less common: SMC, Microdot, HN, etc... I have
observed that BNC and N connectors do come in other than 50 ohm. The
higher impedance connectors usually have a smaller diameter center pin
for the same size finger stock shield connection (plug). Beware that the
higher Z plugs will mate to a 50 ohm receptacle, but the center contact
is very unreliable - a loose fit. For non-critical applications, I have
made them work by carefully increasing the pin diameter using silver
bearing solder. [| = pin; () = solder: (|)]. I don't think I would
do this if the connection was crucial or difficult to access for
repair/replacement.

Recently on the Art Bell show, Art and Whitley Strieber discussed the possibility of amateur astronomers and amateur radio operators conducting a project to monitor the Hale-Bopp comet. I've devoted a page on my web site THE MARTIAN ARCHIVES to the comet, and have posted an article with "brainstorming" ideas on modifying and/or building equipment for the project. Any suggestions will be appriciated! The URL is:

I have five large boxes full of vintage radio tubes (mostly pre 1950s for sale. There are at least 1300 or 1400 tubes in this lot -- I don't have the time to count or sort so I am guaranteeing 1000 tubes!!
tubes are mostly boxed -- maybe some loose ones due to boxes falling apart from age. Some tubes maybe used or retests. There are no modern TV tubes or compactron garbage in this lot!

I am asking a firm 300 dollars. I prefer to have the buyer pickup so the tubes can be examined before purchase. I will ship -- but only on an "as-is basis," you buy'em, you own them. Please note there are no 45s or 50s included! Treasure hunters take note! They were never there, or are long gone!

I live in northcentral Connecticut, town of Somers. Near I-91

call 860 749-7186 for info, ask for Peter, or email me.

As far as I know the only difference is the size of the hole through
which the outer insulation passes (the 75 ohm RG59 cable is larger
diameter). Since both sizes of connectors mate with each other I doubt
that there is any real impedance difference.

For solenoid-wound, air-core coils, the diameter of the wire
has relatively little effect on the inductance of the coil,
compared to the effect of the number of turns, the diameter
of the coil, and the turn spacing.

This tends to hold true for core-wound inductors as well.

For non-precision applications (such as yours) choose a wire size
that fits the size core you are using, is easy to wind, and will
handle the expected power level.

Jim N6OTQ
P.S. Before you flame me, use the equation for solenoid-wound coils
in the ARRL handbook, and play with the variables first. And take a
look at the effect of _total wire length_ on inductance while you're
at it.

Tom,

I bought ITU's PIC-1 programmer a little better than a year ago and have had no problems with the device. The kit was easy to assemble and resonably well documented. It has performed flawlessly for the past year on my personal hobby projects.

On the downside: When I purchased the kit from ITU, they indicated that new software implementing some features found in higher priced programmers was "in the works" and should be released "in the spring". Unfortunately, this has not happened. Furthermore, Microchip has released several new uP's which would be fun to work with. I have emailed ITU a couple times asking about the long awaited software release and have received no response. Since the time of my purchase, ITU has brought on several new products which they appear to be pushing rather than their own designs. There appears to be no long term commitment either to maintain their own designs or support their previous customers.

If I were to do it over now, I believe I would get a programmer (such as the PIC Start-Plus) from a company I know will support their product long term. I believe the differance in price between the low end programmers Microchip sells and the smaller guys can largely be attributed to support. This support means your hardware will not be outdated in less than a year!

Just my $.02

Yes, 50 ohm BNC's have rounded tip on inner conductor. 75 ohm have sharp point on end of inner conductor. If you'll look at the hole in the back of the tip, where the coax inner conductor is soldered, the one for 75 ohm coax is too small by a whole lot to accept 50 ohm coax.

I built the TenTec 1209 2m to 6m transverter. All in all a very
nice kit and a pleasure to build. The only thing I changed was
to add external keying of the T/R switching since the RF sense
switching circuit did not work well on SSB. Easy enough to do
though.

> I get Q about 1 with the added resistance.

The fly in the ointment is that we don't yet know what the series R of a 70nH ni-cr-fe alloy Ls is at VHF. Another complication is that the (VHF) resonant frequency through the suppressor resistor, Rs, is not the same as the resonant frequency through the (more-inductive) suppressor inductor,

Ls. Yet another complication, is that a "low VHF-Q suppressor retrofit kit" consists of more than a lossier Ls/Rs suppressor. Virtually all silver and copper conductors in the amplifier's anode resonant circuit (longer that about an inch) are replaced with ni-cr-fe double-wire conductors, spaced about 1cm apart. Since one of these wires is longer than the other, a staggered VHF resonance is created, like that from a VHF suppressor. Thus, virtually all conductors between the anode and the tune capacitor become more resistive to the flow of VHF currents. . This in turn reduces the VHF voltage gain of the amplifier tube. The before and after difference in the anode resonance dip is readily observeable on a dipmeter.

> Adding nichrome lowers the HF Q, slightly reducing effects of excessive
> drive, exciter transcients, and improper tuning. It does NOTHING for VHF
> stability.
>
Is this a recording? ---something like no significant VHF current flows in Ls?

Tom: How about doing the calculations to show us how much such a suppressor lowers Q in an AL-80?

I do not understand how a reduction in HF tank Q could ameliorate the effects of excessive drive. Please explain. // In the September issue of QST magazine, there is a photograph on page 17 of the innards of an 8873 that was removed from a Henry Radio Co. 2K-Ultra amplifier. The drive level was reportedly over triple Eimac's recommendation. Both 8873s failed. As can be seen from the photograph, the cathode's emissive-coating has been extensively stripped away from the cathode. However, there is no apparent evidence of sputtered gold. When I viewed this 8873 through a 50 power microscope, the gold plating on the grid cage appeared to be undamaged. I saw zero gold melt balls on the cathode. However, when I looked at the tube on page 16 through the microscope I saw numerous gold melt balls on the cathode---yet the cathode damage was minimal. Any comments?

Tom: Have you ever looked through a microscope at the cathode and grid of one of the 3CX800A7s which you claim failed from excessive drive? If you will donate such a tube to me, in the interest of science, I will open it, photograph the innards, and post the photograph on my Home Page at: http://www.vcnet.com/measures/

> > Regards,
> > Jeanne
> >

If you have BNC connectors, then the 50-ohm and 75-ohm
version have two differences:

1) the center pin in the 50-ohm connector is larger diameter
than the 75-ohm connector,

2) the female 75-ohm BNC contains just the female metal contact in the
center of the connector, while the 50-ohm BNC has a plastic
shroud surrounding the female metal contact in the center of the
connector.

If you try to fit a 50-ohm male BNC into a 75-ohm female BNC, you
will deform the metal contact, making it intermittant, or in the
worst case, breaking it.

The plastic shroud of the 50-ohm female BNC makes it more difficult
to mangle or deform the metal contact compared to the 75-ohm female
BNC connector which offers no protection to the metal contact.

>(Note: parallel circuits have susceptance (Y). Series
>circuits have impedance (Z).

Actually, either circuit can be represented in either form. It is just a matter of applying the transform equations in either case to get the other representation. The main reason to choose a particular representation over the other is that one may be easier to work with on a Smith Chart than the other in a particular mesh.

>For any parallel circuit there is a series
>equivalent circuit. For any series circuit, there is an parallel
>equivalent circuit)

Read those last two sentences over and over again until their meaning sinks in, Rich. Adding series resistance to the suppressor coil is equivalent to using a resistor of lower value in *parallel* with a nearly lossless coil. *Exactly* the same with regard to suppressor Q. Thus there is no advantage to using coils made of resistance wire instead of using a slightly lower value parallel resistor to acheive exactly the same suppressor Q at VHF.

Q = X/Rs or equivalently Rp/X

So to achieve low Q, you can either increase series resistance *or* lower parallel resistance. The actions are equivalent with regard to suppressor Q.

At HF, however, the series resistance increases circuit losses over those of the paralleled lossless inductor and low value resistor because part of the HF current flows through the lossless reactance in the parallel case (and part through the low value resistor) while having part flow through the lossy series resistance plus lossless reactance (and part through the higher valued parallel resistor) in the other case. In this latter case, losses are greater at HF than at VHF, which is exactly *backwards* of the behavior we want from a VHF suppressor. These extra losses are unnecessary and unwanted. So use of a lossy coil in a VHF suppressor for an HF amp should be avoided. It offers no benefit in VHF Q reduction over the lossless coil paralleled by a low value resistor, but does increase HF losses.

All this should be immediately apparent when you graph the S12 parameters of the two circuits. And indeed I used ARRL Radio Designer to do just that. At 112.25 MHz, the two suppressors (both designed for a Q = 1 at that frequency) had essentially

the same loss, but at 18.75 MHz the one with the lossy coil (5 ohms ESR) had twice as much loss as the one with the lossless coil. As X declines with declining frequency more current is hogged through the series resistance where it is dissipated. With the lossless coil, as X declines with frequency, more current hogs through the lossless reactance and *isn't* dissipated. Fascinating how that works.

Now, however, if the instability is *really* at HF (or below) and not at VHF, then the lossy coil and higher valued parallel resistor become an advantage because both paths offer increased damping losses at HF (and below) over the lossless coil design. But you insist the problem is *VHF* instability instead of HF instability (or flashovers). Yet the extra losses of your suppressor design all occur at HF (and below), not at VHF. So if they offer any net benefit over conventional suppressors, it must be because of their extra HF damping. Thus you should call them "low *HF* Q" suppressors instead of "low *VHF* Q" suppressors, and revise your theories of the mechanics of the failures to match the observed results.

Of course operators *could* just increase the loading on the amp when they tune it, and acheive the same lowered HF Q, but then I guess you wouldn't sell any suppressor kits.

On my GG amps, I've always advanced loading a bit *past* the point of maximum output when tuning up. I was taught that overcoupling makes them a bit more linear at a slight cost in efficiency. It would also tend to make them a bit more stable (if they had a tendency to be unstable in the first place), but I hadn't considered that before starting to analyze this thread.

3902. 1000 early tubes SOLD!!!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-12 00:00:00 UTC
From: commquart@aol.com
Message-ID: <19961212201900.PAA12954@ladder01.news.aol.com>
Source record: 99742

Please, no more calls or email, the 1000 early radios tubes
have a new home!
Thank you to all who wrote or called!

Peter

>unplausible arguments to the contrary.

You keep dancing with that straw dog, Rich, but it won't hunt.
You *cannot* treat the L branch as separate from the R branch
of the suppressor. Their currents are combined in and out of
the suppressor according to the phase angle between R and L,
and they must be treated that way in order to understand the
suppressor's effect on the external circuit.

As even you have now admitted, the circuits are series and
parallel equivalents. If I give you two suppressors, each
concealed in a cardboard tube, and you cannot tell them
apart by measurements at a VHF frequency, would you concede
that they are functionally identical? Because if you will,
I can make two suppressors, one using a coil wound of silver
plated wire and the other wound with nichrome wire, and
you won't be able to distinguish which is which by measuring
them at the VHF frequency marked on the cardboard tubes.

The parameter of interest for the suppressor is Q, and measured
at the suppressor's terminals, Q at some selected freqency can be
the same for a suppressor made with nichrome wire or silver wire,
as long as Rp is adjusted appropriately for the equivalent of the

Rs in the lossy case. And I'll certainly do that. How the currents divide *internal* to the suppressor are irrelevant. You can't measure them because I've put the suppressor in a sealed cardboard tube, and there's no way you can tell by measuring at the external terminals of the suppressor at the marked VHF frequency.

Now if I allowed you to take a *HF* Q reading, however, you would be able to tell them apart. The suppressor with the lossy inductor will have lower Q at *HF* than the one with the lossless inductor. Thus the things you build are low *HF* Q suppressors, not low *VHF* Q as you tout them.

>> You realize if the nichrome in the suppressor's winding of wire does not
>> significantly lower VHF Q, then everything you attribute to VHF
>> oscillation must be a product of vivid imaginations, or directly

>
>I do not realize that resistance wire (nichrome) has no effect on VHF-Q. I
>have observed that the VHF dip in amplifier anode circuits is rather
>different when silver-plated strap suppressor inductors (Ls) are replaced
>with a resistance wire Ls. With silver (and copper), the dip is sharper
>and deeper. With the resistance wire, the dip is broader and shallower.
>With roughly equal currents flowing in Ls and Rs, why not?

Wrong reasoning. A deep dip means the GDO coil is being heavily loaded. The external circuit is presenting such a low impedance that it is actually sapping measurable current from the oscillator. A shallow dip indicates the GDO coil is being loaded by a higher impedance, which is sapping much less current from the GDO oscillator.

For an LC circuit *in isolation*, the lowest impedance point is the resonant point. But you aren't measuring an LC circuit in isolation, and a low impedance may not be what you need to make the circuit oscillate.

Now, if the anode of a tube is presented with a high impedance at some frequency, how will that affect voltage gain at that frequency? Voltage gain is the product of the tube gm and the anode load impedance, so a higher impedance at the anode represents a higher voltage gain, and a low impedance at the anode represents a low voltage gain. So the frequencies where you see deep dips are the frequencies where the circuit has the *least* voltage gain.

Now certainly phase shift is involved too in the making of an oscillator, but frequencies where the circuit has high gain are more likely to be candidates for oscillation than frequencies where the circuit has the least gain. So frequencies where your GDO indicates deep dips measured at the tube anode aren't likely to be frequencies where the amplifier may break into oscillation.

That's why the frequencies you measure with your GDO don't match
with the ones Tom measures with his network analyzer. He's actually
able to measure S21 (the output to input feedback parameter) of the
operating amplifier with his tool, you can't. And he can resolve
the complex phase of that path, so he can know where the feedback
is positive and where it is negative. You can't do that either.
But I hope you understand that a frequency where feedback is
negative *won't* be a frequency of oscillation no matter how
deeply it dips your GDO.

The GDO is simply the wrong tool for this task.

Selling;
Clemens SG83C solid state signal generator. With manual, clean and working. Calibrated to my HP counter and Boonton 92. 1960's vintage, uses common semiconductors, easily repaired. Covers 50kc to 54mc in six ranges. will run on 117 AC, or from internal 9 volt battery. Calibrated output to over 100k. fairly stable. AM modulation. Selling only because I have three and need only two. $100.00 firm.

Also, clean Boonton 91 RF millivoltmeter. Tube version. Have the 50 ohm termination for the probe for DBM measurements. Don't have the probe tip, but easily made. Have a newer 92AS2 -- need two like a hole in the head. asking $90.00, but will dicker on this unit.

Since no broadcasting of the type you mention is permitted in the
US on 92KHz, I can only assume that what you are talking about is
an FM broadcast receiver with a built in SCA (subcarrier)
demodulator.

SCA is a fm modulated subcarrier (typically at 67KHz but can
be higher) which rides on the baseband of a conventional FM
broadcast station. This is similar to the SAP channel on
modern televisions. You would need to build an SCA demodulator
and retrofit a standard FM receiver with it. You can make your
own using an NE565 IC from Philips (National also has something
similar but I don't remember the part number). Also Ramsey
Electronics sells a kit. Either method requires a reasonably
good understanding of electronics since you will have to
modify the original FM receiver, usually with no schematic.
You would need to consider the time and expertise involved
with the cost of the "special" receiver.

Good Luck

> distinguish them?
> Dave KE9ED

Its easy if you have the two together. The only difference is the
pin diameter (and, of course, the insulator which holds the pin
in place).

The thicker pin is the 50 ohm one.

Putting a 75 ohm BNC plug onto a 75 ohm socket may or may not work,
depending upon if the pin touches or not - it certainly won't be
a reliable connection. Putting a 50 ohm plug onto a 75 ohm socket will
destroy it - one half of the center connector on the socket will
break off - I have seen this happen too many times. And guess
how easy it is to find 75 ohm BNC sockets ?

Philip

Tom,

My documentation states that 50 ohm and 75 ohm BNC connectors are intermatable. That is, there should be no destructive metal deformation when mating a 50 ohm male BNC to a 75 ohm female BNC. In fact, in the only data book that I could find that has dimensions for both series (Kings RF Coaxial Connectors), the diameter of the inner pin is the same for both the 75 and 50 ohm male connectors (0.052-0.054 inches). And all of the databooks that I have (Kings, AMP, and Berg) state that they intermate.

If there is documentation that states otherwise, I'd be grateful if you could point me to it.

Generally, for many applications it will not matter which type of connector one uses. I just checked both a 50 ohm and a 75 ohm version of an HP 3570A Network Analyzer that I have here, and both use the same style female BNC. Ditto for my Tek Vectorscope and Waveform monitor. At the low frequencies in which these are used, given that the BNC's

are near either the source or the termination impedance, the flavor of BNC doesn't matter.

Hmmm...does anyone know at what frequencies the selection really starts to matter? Suppose I have two 40 foot pieces of 50 ohm coax to connect between my 50 ohm generator and a 50 ohm load that's 80 feet away. If I use a 75 ohm barrel instead of a 50 ohm barrel, at what frequencies will I start to see an appreciable difference in performance?

I suspect it's when the barrel length becomes an appreciable fraction of the wavelength of the signal.

Heh, as you see the usual ham reaction to this is "HORRORS!" There is a
circuit for a 2 meter transmatch circuit in the old ARRL VHF Manual.
I built one years ago (it will only handle 100 Watts or so max) and
found it quite useful for coupling power to all sorts of things:
*Horizontal and Vertical Beams tied together with T fitting
(very useful for VHF nets where horiz. polarization is used by some
checkins and vertical by others)
*TV and other off frequency VHF antennas
*Long wires, HF beams and other non-VHF antennas
And, yes, none of these work as well as a resonant antenna and matched
feed system without additional matching circuitry on the wrong (radio)
end of the coax. They do provide experimentation and some utility
though.

Hi Chris--

My understanding is that the Ten-Tec and Downeast units are both good. I have worked several of each on the air, and the owners I've asked seem happy with them. As I recall, the Downeast unit runs a bit more power which is helpful for driving 25-W input amplifiers.

I've noticed that even on the finest of video equipment, the
manufacturers use 50 ohm BNC connectors in a 75 ohm system.
The difference is probably not worthy of thought at baseband
video frequencies but might be at higher RF.

Hmm - I have worked with both and have seena *distinct* difference.
I have also had to replace more than one 75 ohm socket destroyed by some
moron
forcing a 50 ohm connector onto it.

I have also traced inrermittent problems to a different moron using
75 ohm plugs to fit 50 ohm sockets, and the pin sitting nicely in the
middle
of the 50 ohm socket without touching the sides, until a tiny amount
of force is applied to the cable.

Differences *do* exist, I have seen them, I have suffered from them.

>P.A. stage at 144Mhz ?

I have. It has always worked well.
I even have a spare should you (or anyone) need it :-)

>I am after the power supply, biasing and de-coupling circuit.

Simple. Just apply 9V to the bias pin (switch it with the TX/RX switch).
This is easily made using a 7809.

I made a simple board by cutting out some areas on a small piece of PCB
material. All supply pins are decoupled close to the device, using a
ceramic cap and a tantalium cap in parallel, and fed via ferrite bead
chokes.
I don't think this was actually in the datasheet, but it "it never hurts".

The piece of PCB is bolted to the heatsink, and two strips of copper are
used to connect the ground area to the mounting flange.

According to G3OSS in the out-of-print RSGB Buyer's guide,
a 50 ohm BNC plug fitted into a 75 ohm socket can cause the metal
fingers to splay out, damaging the socket. Conversely, the 75 ohm
plug fitted into a 50 ohm socket may be intermittant.

OTOH, Amphenol claims to make a line of 75 ohm connectors
with the feature of intermateability with standard 50 ohm BNCs.
Looking at an old 75 ohm Amphenol coax switch, the female center
pins are a little smaller.--Zack W1VT

>(0.915) * 40.3 ohms = 36.9 ohms. The R vector is cos 66.22 degrees (0.403)
>* 40.3 ohms = 16.2 ohms.
>
>Finally, using Q=X/R, Q = 36.9/16.2 = 2.28. Thus, your answer of Q = 2.3
>looks good to me, Tom.

Or you can skip all that monkey motion and simply use Q=Rp/X.
For Tom's example, 70nH at 100 MHz is 43.98 ohms and R is stated
as 100 ohms (not 50 as you mistakenly use above). Dividing

100/43.98 = 2.27, or rounded, Q = 2.3.

I'll leave it as an exercise for you to discover your error(s) in the
above gyrations that allowed you to come up with the right answer after
starting with the wrong value for R.

>

Rich,

Maybe its time to ditch these interminable Q calculations, and actually
meaaure the VHF response of an amplifier with and without your
suppressors.
It shouldn't be that hard to hack a VHF input circuit onto an HF amp,
drive it with some low-level VHF source, and see what shows up at the
anode.

The purpose of theory, after all, is to model reality. It's
time for a reality check.

While you are at it, you could also check on what fraction of the total
anode VHF voltage appears at the HF tuning cap and band switch.
Conventional
wisdom says not much; you say enough to be a source of failures.

The best way to have your claims taken seriously is to demonstrate the
existance of the proposed effects in some repeatable, analyzable way.

>resonance frequency.

Neutralization is a technique which can be used at any single frequency where instability may be a problem. It is not limited to the operating frequency.

A related concept, called unilateralization, attempts to neutralize the amplifier at *every* frequency for which the amplifier has gain. This can require a much more complicated network than is needed to just neutralize at a single frequency of course.

Better is to just design the amplifier from scratch to be unconditionally stable. That's the way the solid state PAs in most exciters are designed. And Tom would like to tell us that it is the way a good GG tube PA is designed too. Dissipative suppressors can play a role in achieving unconditional stability, of course, but they aren't the only way to achieve it.

Been looking for an easy, inexpensive ($13.90 single quantity) way to connect your hobby to your

PC? Then please read on!

E-LAB Digital Engineering, Inc. announces the release of their new

EDE300 Interface IC. It allows for convenient flow of data either from a

PC ot too a PC via the serial port. Our datasheet even provides

software examples for use with a PC. NOW IS THE PERFECT OPPORTUNITY TO INTEGRATE YOUR PC INTO YOUR ELECTRONICS PROJECTS!

Our datasheet is available in electronic format via our webpage at

http://www.netins.net/showcase/elab or contact us directly at

elab@netins.net and include your postal mailing address.

In addition, we will do our best to get you up and running when using

the EDE300, even if your electronics experience is limited.

Todd Peterson

>Reference Data for Radio Engineers where it clearly shows "NBS".
>

Sorry, Wes, you're right after all... well, kind of.

None of my British handbooks mentions NBS, and neither did US sources such as the 1950 ARRL Handbook or the 1959/60 and 1977/78 editions of the Handbook of Chemistry and Physics.

I finally found it in the 1941 edition of Machinery's Handbook:

"This Standard Wire Gage (also known as the Imperial Wire Gage and the English Legal Standard) is used in England for all wires. The abbreviation S.W.G. is sometimes used for Standard Wire Gage, also the abbreviation N.B.S. for New British Standard Wire Gage. This gage was legalized in Great Britain in 1883."

It seems that Reference Data for Radio Engineers uses wire tables that date back to the days when NBS really was "New"!

3926. Re: 28Mhz to 144Mhz Transverter using M55727 Mitsubishi RF Power Module

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-13 00:00:00 UTC
From: Niels Montanana <nielsm@lcpub.co.uk>
Message-ID: <58s55a$tni@alpha.ftech.net>
Source record: 99644

I put the PA stage together using the M55727 module and
everything works great.

I have a small pcb, 100mm * 25mm, parallel to the module and
bolted to the heatsink on a couple of spacers so that the
module pins lie flat on the PCB.

I put ferrite beads on all the power leads + decoupling caps
and feed the bias in via a 7809 regulator.

The PA stage forms the 'final' of my homebrew 28Mhz to 144Mhz
transverter which makes a lot use of MMIC's and Toko helicals
with an MGF1302 RX front-end.

Power output is variable from 0 to 20W with 28Mhz drive from a
Yaesu FT100MP.

If anyone would like circuit details please send requests via
eMail to nielsm@lcpub.co.uk

I had just such a repair on a Heath scope years ago and spent quite a
while looking for alternate sources of HV diodes. In the end I could
find nothing except for Heath above 200 V. Keep in mind that it is
perfectly legitimate to add a few more diodes to your string and use
smaller values.

BTW, the problem with my old scope was that the Zener voltage varied
considerably with temperature on SOME of the Heath Zeners. I bought
extras and selected ones that were stable. This corrected the dimming
as it warmed up problem that it had always had! Using more standard
diodes might also be more reliable in this way.

In one word, DON'T.

In a few more words: match the impedance correctly at the antenna itself
and operate the feedline at low VSWR to reduce losses. If your antenna
is not matched correctly, it would be bad engineering to build an ATU to
hide the problem - fix the antenna.

Subject: Coax connectors impedence

Hi,
I have a dumb question I hope someone will help me with. I have some
coax connectors I bought to use on a homebrew antenna. I don't know
now if they are 50 ohm or 75 ohm impedence. (I didn't realize it when
I bought them and they aren't marked.) Is there an easy way to tell?
Would 50 ohm connectors have some physical telling difference or can
I measure them with me ohm meter to tell?

Thanks for your help.

Date: Wed, 11 Dec 1996 17:09:04 -0500
From: Larry Robison <robison@amnorth.com>
Subject: Coax connectors impedence

Hi Jeanne:

Connector impedance isn't as confusing as it may seems. The only connectors that are true 50 ohm connectors are "N" and "BNC" connectors. The thing that establishes them as constant impedance connectors is the dimensions of the center conductor pins and the interior dimension of the shell. As in a piece of coax this is the primary thing that determines impedance. The impedance of the connector is really only important in feedlines that are used on frequencies above 30 Mhz. It used to be that only the purists were concerned with 50 ohm connectors because they were always somewhat more difficult to install and were more expensive than their counterpart the PL259.

The PL259 is the old standard for most amateur work because they were readily available, cheap, and fairly easy to install. They will handle the power that most amateur equipment produces, all the way up to a couple of kilowatts without too much trouble. Since their design is not such that they qualify for being a "constant impedance connector" they are used in either 75 ohm cable or 50 ohm cable with equal success.

The PL259 adapters that state that they are for RG58 cable or RG59 cable has nothing to do with impedance. It more has to do with how snugly they fit around the cable, thus preventing physical movement from destroying the integrity of the connection.

I hope this helps.

IMO, the magnetic characteristic is probably a factor at VHF. By adding a
small amount of iron to the basic nickle-chromium 4 to 1 ratio, the
hysterisis-loss increases noticably at 50MHz. It will be interesting to
see what happens above this frequency on your Boonton 250, Wes.
Another issue is that there are two, different, anode VHF resonant

frequencies whenever a VHF parasitic suppressor is used. The higher resonant frequency is through the suppressor resistor, Rs (the lowest L path through the suppressor). The lower resonant frequency is through the more-inductive suppressor inductor, Ls. (Note: Rs and Ls act independantly because the magnetic field from Ls is at a right angle to the magnetic field from Rs, Thus, a stagger-tuning effect is produced.)

A nichrome Ls does increase HF loss by roughly one percent on the 28MHz band. Unsurprisingly, nichrome does exhibit heating during operation at 28MHz. I would be concerned if this were NOT the case.
About 30 years ago, an old timer told me that he built a ten meter antenna with stainless steel screws, and that during operation the stainless steel screws became so hot they melted the plexiglass insulators they were screwed to. (Most types of stainless steel are a mix of nickle, chromium, and iron.)

Subject: Regency Handheld 2m for Trade for homebrew parts

I have a Regency Micro Com PH-251A handheld 2m rig
I'd like to trade. It's only a single channel, and not
even on a ham channel! Currently crystalled for
151.805, xmt and rcv. Has slots in PCB for a number of
additional xtals if you felt like putting them in.
This is the standard Regency handheld of old.

With leather case, and Wilson BC-2C charger base. NiCad
in good shape, radio works very well. With 'duckie' antenna.
Tuned it in on my scanner and it sounds great. 1 watt or
5 watts switchable. External mike/spkr jack in top. Very
good physical and electrical shape

Just needs xmt and rcv rocks for a repeater or simplex pair.

What do I want? $30 plus shipping :(or homebrew parts.

Here's what I'm after:

Vernier dials - the kind you can put a label behind
like the old Johnson series

3-section 1100pf Variable caps

Stripped SB-xxx Heathkit chassis (no parts) - want for
homebrew project

SB-430 Station Console (thingy with the clock, timer, and SWR meter)

500-0-500v 100ma range power transformers - anything close

Coil stock of any airwound flavor

Little unfinished RF / Ham projects that got started and never
finished that have nifty parts inside

Any combinations of the above.

You get the picture....I do alot of homebrewing these days, and my junk box is
as empty as my wallet!

Email to: Dave gekko95@ix.netcom.com

Subject: Schematic Drawing Software For Ham Use?

Since you chose not to answer my question let me say:

I have tried CirCad.
The shareware version I tried had crude menus in the manner that a beginner
would make. As if there was no attempt to take the look of the system beyond essential stuff that was available 10 or more years ago. I would think
a program that costly would upgrade to a stylish version like the rest have.

YOU are correct. No support.

The documentation available was really no documentation compared to any other
CAD programs.

Many other CAD programs, shareware that is, and one in particular- DraftCHoice -
makes CirCad look childish.

Hell, Easytrax, can be made to draw schematics, does all the CNC Gerber stuff and it is freeeeeeeeeeee.

If Harvard Garphics 3.0 for DOS would allow .025 inch snap spacing on 8.5 x 11, I wouldn't need anything else. Not even AutoCad.

CirCad, the version I tried, has a value of less than $50. The best version
of DraftChoice is $99. There are many better deals.

Schematic capture? Can't draw the schematic if you can't understand the program.Net list? Bus? Come onnnn.

Carl

CirCad software -$995.00

This huge support factor was created by the manufacturer to justify the $995 cost I quess. The support was equal to more that $700 of the cost of the program. ...more that $700? You are getting it for less

that $295? Right? Per program I should say. Right again? Where could I find an organization that spends 70% of its income from a product to pay for support. That only leaves 30% for rent, utilites, return on R&D...you know what I mean.

Not my concern really just curious but will you explain this lack of support the ham version provides?

Carl

From: Peter Lascell <plascell@inmind.com>
Subject: Stancor Poly-Pedance Mod Xfmr taps

Does anyone have an instruction sheet for a Stancor A-3893 (1960 vintage) or other "Poly-Pedance" modulation transformer of the A-389x series. Need the taps and jumper connection chart to match impedances.

These transformers were for a multitude of impedances as reported in their catalogs and were used in the ARRL Handbook for one or more modulators around 1960-1965. But the construction articles never specifically identified the taps to be used, rather refered the user to the instruction sheet packed with transformers to determine which taps are shorted and which ones are used for the plate connections. The operating current & voltage determined the impedance and tap adjustments were required to get the ratios right.

To be sure I get your response if you can help, please copy to:

>Anybody?

I haven't built the 440 rig, but I did build the 2m rig. The modulation
is just summed into the PLL error loop, and if you've been following the
9600 baud threads, you know that's not going to work correctly.

The radio sweeps the VCO to the various receive and transmit offsets
by mixing offset reference crystal oscillators with a sample of the

VCO in the PLL mixer and feeding that to the PLL chip to generate the loop error voltage to steer the VCO to the proper frequency. You can't use it duplex or split it.

The 2m radio had a *number* of design flaws (I can't claim the inability to do 9600 properly is a design flaw since most other synthesized radios share it, and it doesn't affect ordinary voice use). But for example, it will transmit with the PLL out of lock, a definite no-no. And receive sensitivity was much worse than specified unless modified from the way the instructions tell you to build it. And the PA would go spurious if you tuned it according to the instructions in the manual (you can tune it clean with the aid of a spectrum analyzer, though you might have to settle for about 3 watts out). There were a number of fixes to its various problems which were posted here when it first came out.

I understand that the design has been revised since the first release. I can't say if any or all of the problems noted in the first units have been resolved because I haven't seen one of the new units. But unless they have been, you don't want this radio except as a learning experience on how *not* to design a radio. There were also problems with component quality. The first radios were sent out with reference crystals which would not net onto frequency. You had to modify the reference oscillators to get them on frequency. Now some of this may be attributed to teething problems of a new product, but most of it is just typical Ramsey.

If you want a transmitter and receiver you can build from kits which will work for 9600 baud, buy the Hamtronics kits. Their quality isn't wonderful either, but at least the design is sound, and they will usually work as advertised after a bit of debugging.

Jeanne;

If they are N connectors, there is a difference. The 50 Ohm N connector has a much fatter pin than the 75 ohm connector. I learned this lesson the hard way. I had a 75 ohm connector mounted on a receive antenna located on a tower at 174 feet. We used a 50 ohm connector and ruined the female connector on the antenna. I had to have a tower crew take the antenna down and repair it.

>>Does anyone have any input on the Ten-Tec 2 meter FM Transceiver that you
>>assemble from a kit?

You will really like building this kit. It should not be your first
kit, as the unit is fairly complex.

I love my TT 2 meter. I always get good reports on sound quality, and
the 15 memories are enough for me. I only talk on three anyway.

The major problem in my book is the lack of scanning capability. I
talked to Ten Tech, and asked them for the processor code, so I could
implement scanning. They refused, but promised that they are working
on an upgrade to allow scanning. I am impressed! This feature alone
will make their radios in the very nice catagory. I have other
Japanese radios with so many features that you can't use, unless you
have the manual in your lap. The Ten Tech units are nice, simple, and
well designed.

The audio of my TT 2m rig is equal to or better than any other radio
on the market.

The tuneup process is critical to the proper input sensitivity of the
unit. If you buy one, I would recommend borrowing, or renting a signal
generator, unless you have a very good busy repeater nearby. I got the
sensitivety down to .18uv by using a signal generator to tweak the
coils.

Have fun!

3933. MRF-247 at 6 meters problem?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-13 00:00:00 UTC
From: akent@bga.com
Message-ID: <58qllq$smc@news3.realtime.net>
Source record: 99767

I have built a 6 meter amp that is using the MRF-247 transistor, and am having trouble with the output. I used the computations in the RF book for the filters and impedence matching networks, but the output is flaky.

The input impedence looks ok, as my 6m meter rig sees about 2 watts of power with a 1.2 SWR. The output swings around with major harmonics on my spectrum analyzer, and changes with time.

I used the Motorola AN791 in the RF applications reports book page 156. I computed the difference in the frequencies from the formulas in the book. Are they correct? I had to modify the input values to get a good input SWR. The output is not what I would expect.

I am currently seeing about 15w output from 2W input, which again changes with time.

I know that this transistor is designed for 2m, but I can't believe that it is not usefull at a lower frequency.

Thank you for you help.

It's tough to give a general answer to that question. All that happens is
that you get an impedance transformation from the connector. It will have
the same effect as an inch or two of transmission line of that Z0 inserted
in the system. Of course, the amount of transformation will increase as the
connector gets longer in terms of wavelength (until it reaches 90 degrees
then will decrease, becoming zero at 180 degrees, etc.). I'd expect the
effect to be negligible for most purposes at least through UHF. In the
microwave region, the seriousness of the effect would depend on where it is
in the system and how matching is accomplished. For a transmitting antenna,
a connector near the source would transform the Z seen by the transmitter,
which might be correctable with a matching network. It wouldn't have any
impact on the SWR on the cable beyond it, so wouldn't increase cable loss.
A connector of the wrong Z at the far end of the cable would increase
cable SWR (assuming the antenna is matched without the errant connector)
and would therefore increase cable loss. In a receiving system, the effects
of placement are reversed.

Jeff Anderson wrote about 50 and 75 ohm BNC connectors:

> And all of the databooks that I have (Kings, AMP, and Berg)
>state that they intermate.
>
>If there is documentation that states otherwise, I'd be grateful if you
>could point me to it.

I ran this topic several months ago in my magazine column, and it generated some useful some follow-up mail.

Yes, in the ideal world of the connector catalog - top-quality, brand-new connectors, perfectly assembled - they do intermate.

But the story can be very different in amateur practice, where we re-use old connectors and assemble them without the benefit of professional jigs and tooling.

A 50R plug will mate with a 75R socket; but if the plug is assembled off-center, the socket may be damaged and become unreliable in the long term. It's quite easy to damage a 75R socket because the end of the inner connector is unsupported. Also, a 75R socket that has been opened out by frequent use with 50R plugs can become unreliable with the more tapered center pin of the 75R plug.

Older-style BNC connectors do not have a captive center pin, and it is very easy for amateurs to assemble them with the center pin "short" or "long". This is more likely to lead to problems when the connectors are not of the same impedance. The more tapered center pin of the 75R plug can be an intermittent contact in a 50R socket if the pin is assembled short... unless of course the pin is also assembled off-center!

What convinced me was someone's experience with a large number of new 75R plugs (ordered by mistake) in a computer network that used new 50R sockets. The network suffered considerable problems with intermittent connections. When all the 75R plugs were replaced by 50R plugs, the problems disappeared completely.

I do agree that the impedance 'bump' within intermated connectors is negligible, up to and including the 2m band at least, but that still leaves the reliability problems and the problem of incompatible cable diameters - 75R cable will not fit into a 50R plug, and 50R cable is not anchored securely in a 75R plug.

Bottom line: I don't buy 75R BNCs any more, or even keep the ones I've been given for nothing, and I'm gradually weeding 75R BNCs out of existing equipment.

The same applies to the older patterns of connectors with non-captive center pins. I wouldn't buy BNC (or N) connectors with non-captive center pins any more, not even at surplus or giveaway prices. The more modern versions have captive center pins which are self-locating and much more tolerant of amateur assembly methods. They also have improved braid and cable clamping, and are much easier to re-use.

I am working on a T-44 TV Transmitter. I understand that this was quite popular in 70's. I have been told that there are articles in QST and information in an earlier ARRL Handbook. I would also like to get copy of the schematic. I would welcome any comments and discussion on the T-44 and video modulators.

Thanks,

Andrew KB3APR

3942. Re: soldering home brew boards

Solder paste and a static hot air source are the ideal way to deal with SMD. A Weller Pyropen Jr makes an excellent static hot air source with the appropriate shroud, and it is inexpensive. But the problem is with the solder paste. It doesn't store well. The brands I've tried need to be stored in a refrigerator if they are to keep for any reasonable length of time. So the home constructor tends to buy just a tiny bit at a time and use it up rapidly. That is inconvienent, and more expensive than buying in larger quantity.

The technique is pretty simple. Put a tiny dab of solder paste on each pad (I use a toothpick for this). Place the component on the board (tweezers are good for this). And give it a shot from the static hot air source. When the solder melts, its surface tension will pull the component into alignment with the pads. Remove the hot air and let cool.

Note that the hot air source needs to be static. An electric heat gun blows too hard. It'll blow the parts right off the board. And hot air is corrosive if it retains a high oxygen content. The combustion products from the Pyropen are depleted in oxygen, so are much less corrosive.

Message-ID: <19961213151600.KAA14061@ladder01.news.aol.com>
Source record: 99777

Rich,

Read what Gary said carefully. It is exactly correct.

In article <1996Dec12.201013.1791@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>As even you have now admitted, the circuits are series and
>parallel equivalents. If I give you two suppressors, each
>concealed in a cardboard tube, and you cannot tell them
>apart by measurements at a VHF frequency, would you concede
>that they are functionally identical?

It does not matter if Rich concedes this or not, it is a fact.

>Now if I allowed you to take a *HF* Q reading, however, you would
>be able to tell them apart. The suppressor with the lossy inductor
>will have lower Q at *HF* than the one with the lossless inductor.
>Thus the things you build are low *HF* Q suppressors, not low *VHF*
>Q as you tout them.

I've said the same thing in almost the same words.

>Wrong reasoning. A deep dip means the GDO coil is being heavily
>loaded. The external circuit is presenting such a low impedance
>that it is actually sapping measurable current from the oscillator.
>A shallow dip indicates the GDO coil is being loaded by a higher
>impedance, which is sapping much less current from the GDO oscillator.

As Gary, Wes, and I are trying to tell you...the GDO (or dipmeter, as your gadget is called) is sensitive to absorbtion of RF only, and MUTUAL COUPLING. The heavier the oscillator coil is loaded, the greater the dip. I can make a deeper and wider dip occur with less Q as well as more, just by changing the distribution of inductance.

This can be seen in a simple circuit by putting a small coil of wire in series with a main inductor of many turns. If the big inductor is dipped, the dip will be sharp and deep. If the small series coil of wire is dipped, the dip will be shallow and wide. Yet the Q of the circuit is unchanged, only the coefficient of coupling is modified!

A network analyzer or impedance analyzer will not be fooled by mutual coupling changes, since it connects directly to the circuit. Whether I measure Q in series with the circuit, or across the small coil, the correct instrument gives almost perfectly identical Q and resonant frequency. Only the IMPEDANCE value changes with the Impedance analyzer.

>But I hope you understand that a frequency where feedback is
>negative *won't* be a frequency of oscillation no matter how
>deeply it dips your GDO.

As Wes, Gary, and I have all said in different words.

Except I won't say "won't", I'll just say it would be the best of blind luck if it were the frequency of oscillation. As a matter of fact, if the PA oscillated on the deepest GDO dip frequency just because I "guessed" it would, I'd quit doing PA's and enter the lottery every week. I would be a VERY lucky person to guess against such odds like that, and would use my ESP in better ways.

Using nichrome makes a low HF Q tank, not a low VHF Q suppressor. Lower HF Q makes the tank smoother to tune, and lessens the voltage slightly of tank voltage overshoots due to excessive drive power. The results you measure may actually indicate HIGHER VHF anode impedance, pushing the system towards oscillation at VHF!

Using thin long leads (even of nichrome) between the anode and the shunt impedance of the plate tuning capacitor is foolish. It demonstates a lack of knowlege of behavior of components in RF circuits. The impedance should be made as low as possible to minimize anode impedance and VHF gain. That's why smooth wide anode straps are used in critically stable applications, and why thin long leads on the grid or anode reduce stability.

Few (if any) of your claims agree with physics or common circuit theory. This is why, when QST finally sent your papers out to independent engineers, the replys came back so negative! If you don't believe that, call them and ask them. They searched and searched, and found no RF engineer who agreed with your explainations.

It isn't an industry, personal, or QST conspiracy Rich. Everyone that disagrees with you isn't "out to get you". You are a very talented and imaginative writer, the imaginative part is probably the problem since this is a technical area. It's too bad no one helped you weed this all out before you went public.

I have no more time for arguments about the value of a GDO or time to correct math or circuit analysis errors. I feel just as bad as you do about the way you were treated, someone should have had sense enough to look this stuff over BEFORE printing it. That was not your fault at all.

Good luck in the new year.

3944. Coax Connectors Impedance

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-13 00:00:00 UTC
From: d.NOrdquest@juno.COM
Message-ID: <19961213.121703.4455.0.d.nordquest@juno.com>
Source record: 99778

Jeanne asked if connectors came in different impedances. Having read that BNC's did, but having seen no differences between specimens I removed from 50-ohm RF and 75-ohm video equipment, I seconded Jeanne's question, only to provoke the following response:.

From: jim@rst-engr.com (Jim Weir)
Subject: Coax Connectors Impedance

d.NOrdquest@juno.COM shared these priceless pearls of wisdom:

->In regard to Jeanne's query, I believe there are 75-ohm BNC's, as well as
->50-ohm types. Could someone more knowledgeable tell us how to
->distinguish them?

Pink and blue booties??

Jim

Since it turns out from the other, more useful responses that a few manufacturers
have apparently used similar pins in both varieties, that some 75-ohm BNC's will mate with 50-ohm types, that some vendors use 50-ohm types in 75-ohm systems, and that there are older and newer types of 75-ohm BNC's, the matter is hardly as simple as Jim suggests. As for the "priceless pearls of wisdom," I thought I was being a gentleman in seconding a question that had provoked a very unkind response. Perhaps in another life I got Jim's goat.

Much of the work done at that time was for black and white video.
It is unclear if the T-44 output circuit is broad enough to pass
color. Also, keep in mind that unless you use a VSB filter on
the output of transmitter, you will be running double sideband
with an occupied bandwidth of over 9 MHz! Make sure you don't
bother any existing users of the band.

Good Luck

>the horizontal sync pulse. This means that unless I can clean up the
>signal, I can't use the pulse as a trigger. Anyone have an idea how
>the signal can be cleaned up? - Mike

The faint trace you are seeing is the vertical sync pulse. When triggered at an H rate, the scope shows you every line in the video field superposed. A number of those lines are the vertical interval (that black bar across the picture when you roll down the vertical hold control on the monitor). This is negative going (with equalizing pulses) for several horizontal lines at the beginning of each video field. That shows up on the scope. In other words, what you are seeing is completely normal.

Slow the sweep speed down to 20ms per division and you'll see the vertical sync pulse in all its glory.

You need a sync separator circuit to separate H and V sync pulses if the circuit you want to trigger can't tolerate the presence of V sync at the start of each field. There are equalizing pulses at twice the H rate during the vertical interval. You'll also need to deal with this in order to regenerate H rate pulses during that period. (If you look carefully at the display you have now, you can see these equalizing pulses as faint pulses halfway between the H sync pulses.)

Gary

3948. Where is Jay? I'm here!

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-13 00:00:00 UTC
From: Jay Craswell <73016.27@CompuServe.COM>
Message-ID: <58s6rm$eo3$2@mhadf.production.compuserve.com>
Source record: 99782

Apparently I'm not setting the ignore options right or whatever. "Jay" is here.
I don't check USENET all the time. I'm working on a bunch of projects for
97 and have not been keeping up with the threads. I do check my E-Mail
almost everyday. If you commented or asked a question about Circad and I
didn't reply PLEASE don't take it as an insult. I honestly do think Circad
is a great program. Heck I use it to generate artwork all the time. And that
(to me) is my main source of income. Well until publishers clearing house
calls. The only reason I got involved with the Ham package was that I saw a
need for a program that Hams & Students could afford that would not require a
bank loan or divorse from the XYL. I did a tiny bit of work on part of the
program and the owners set up a special site license for Hams in general.
My company does the support (Yes really!) and you do get the manuals and can
get updates for $50. Someone started the rumor that you don't get manuals and
there is no support. I love talking Circad and I happen to think I know most
of the answers. Plus since I work late hours you can phone when the rates are
lower. So support is around through Dover. Manuals etc? Of course!
I keep hearing about a shareware version of Circad. There is not and never has
been a shareware version. There is a FREE demo. This allows you to try the
program. It does not have all the features but will give you all you need to
know if it works. The Ham version $295 is the complete program. Same software
as the $995 version but no support from Holophase. Your stuck with Dover.
Updates are also not free. $50 per update whenever you decide to update.
Yes, if you have the program for 4 years and never update you can update for
$50. No auto Extortion policy like some others... So, flame off ok?

Wes Stewart (n7ws@azstarnet.com) wrote:

: In article <32AF52D5.277F@compulink.gr> Apostolos Bouroussis writes:
: >Please where i find a list that explain the diameter of the wires that
: >is coded by numbers.

: I believe, that the numbering system stated probably is AWG (American Wire
: Guage).

: There is an approximate formula for comverting these numbers to diameter, but
: I don't have it at hand.

For those with calculators or spreadsheets who would like to ditch
their wire tables:

Diameter in inches = 10^(-0.05035 * AWG_number - 0.4884)
Diameter in millimeters = 10^(-0.05035 * AWG_number + 0.9164)

Accurate to better than 0.1% (around 0.02%?) (Like to see you
find wire that's drawn to that sort of accuracy!). Use -2 in
formula for AWG 000, for example.

(Also, DC resistance, ohms/1000 feet, at 20C, is very nearly
10^(0.1*AWG - 1), though this is not as accurate as the
diameter formula above...just easy to remember.)

(Guess if you like 10's a lot you could remember that as:
R1000 approx= 10^((AWG-10)/10))

How could we be sure that the measurement apparatus did not alter the nature of the input and output circuitry?

> While you are at it, you could also check on what fraction of the total
> anode VHF voltage appears at the HF tuning cap and band switch.
> Conventional wisdom says not much; you say enough to be a source of failures.

Conventional wisdom says that such failures are not possible. // Measuring the phenomenon may be more complicated than it looks, Andy. Although minor levels of VHF energy can be observed at the anode with a spectrum analyzer whenever the anode current changes, however, when full blown regeration occurs---i.e., the kind that produces arcing--- it appears to be quite brief. // I have no doubt that the mysterious arcing is related to the presence of regenerative VHF energy. Consider an amplifier which produces a maximum of 2700v peak at the tune capacitor, whose bandswtich has a measured holdoff V capability of over 5500v. If the bandswitch arcs when the amplifier is not being tuned up, and/or is not being overdriven, it seems likely that there was an anomaly during the arc.
.

> The best way to have your claims taken seriously is to demonstrate the
> existance of the proposed effects in some repeatable, analyzable way.
>
I have little hope that Mr. Rauch will ever take anything seriously if it contradicts his dicta. For example, when confronted with the results of his own problem on the magnitude of VHF currents in an Ls/Rs VHF parasitic

suppressor, he summarily dismissed the results. // Consider the long and winding road over the question of whether or not the AL-1500 uses a VHF suppressor. // Consider the case of Buzz Miklos, who used to work at Eimac-Varian's Salt Lake City plant. Mr. Rauch told us "that Mr. Miklos was indeed R+D engineering manager for Varian". However, when I telephoned the personnel department at the Salt Lake City plant, they told me that Mr. Joseph 'Buzz' Miklos' title was "Engineer B"---and they assured me that Mr. Miklos was NOT the R and D Engineering Manager.

Hi,

I am just getting started making my own PC boards and
intend to utilize toner from a laser printer to mask the traces
before etching. My question is this, I about to try using a
product called Toner Transfer System. It is a paper you print
on that has a water soluable coating. You iron it to transfer
the toner to the copper and then soak in water to release the
paper. Simple enough, but the paper costs $3.00 a sheet and is
a one use product. I have heard that some folks use plastic
transparency film to achieve a similar effect. How does this
work? How do you do it? Is there any particular brand of
transparency that works best?

Thanks,

Ever tried circuit maker?
Much better to my opinion! Much more serious! Much more 'the real world' in transistor parameters, measurement results etc. Also Microcap is quite interesting too (Version 4) although, quite expensive!
Good luck anyway!

Regards,
Marc

John,

Could you elaborate? Your explanation seems counter-intuitive because the the VCO of a PLL is usually fed with a low-pass filter. Shouldn't it be that higher frequency noise is cancelled by the PLL? It seems that the only noise components which could modulate the VCO would be low frequency noise components which are below the cut-off frequency of the low-pass filter. Perhaps I'm overlooking something . . .

Thought he was makings measurements on a Boonton 250 RX meter?
I have a vintage Boonton VHF Q meter, but I don't think it is of much
use for very low Q values.

I have a question. Probably shouldn't ask it, but I am going to
anyways. What would happen if the parasitic suppressor was made
to be parallel resonant at or near the parasitic frequency. I know it
would require an additional capacitor -- but I was wondering if this
wouldn't solve a few problems. First the coil size could be reduced,
limiting losses at 28 MHz. Secondly, there would
be little doubt that most of the VHF currents are flowing through the
resistor.

Another factor I have not seen discussed is how the suppressor
resistor appears at VHF. There has been a lot of complex math thrown
about, but all the calculations to date ASSUME that the resistor has no
inductance or capacitance and has no reactive components . Anyone
who has tried measuring a resistor on an RX bridge -- even at HF --
knows how imperfect most resistors are.

The most interesting "suppressors" I have seen were used by Hallicrafters
in an AB1 amp using a pair of 4CX350 tubes. They used wire wound
resistors, with a heavy wire coils wrapped around them!

Snip....

Just that has been done and has served me well without a glitch in 15
years.

In an article entitled "Five band Kilowatt Amplifier" in the January
1974 issue of "Ham Radio" magazine, W4OQ used such a device on a 4-1000A
amplifier. I built this project, and the amp is going strong to this
day with same tube I started out with. Here is the "recipe"....

20 pf ceramic capacitor (Centralab 852S, which was a "mini-doorknob
with axial leads) in parallel with four 470 ohm two watt resistors and
four turns #12 wire, one half inch diameter, resonated to 110 mhz.

John went on to say in the article:
If you look carefully at the physical structure of the grid and screen
of the 4-1000A, you will see that they form a sort of basket-woven
cavity. When a positive voltage is placed on the screen, these cavities
(with the filament) act as a triode oscillator above 100 mhz. By way of
demonstration, if you ground the grid and screen of the 4-1000A and
couple a GRID DIP OSCILLATOR to these leads, you will find that the
screen is resonant at about 120 mhz. The grid is resonant at about 110
mhz, an ideal condition for REGENERATION. Under these conditions, the
screen is inductive in respect to the grid, the condition required for
in-phase feedback.
"In fact, a 4-1000A self-oscillates near 110 mhz, and the 4-400A at
about 140 mhz. A pair of parallel
power tetrodes may act like a push-pull oscillator, oscillating at a
frequency that is dependent on the length of their interconnecting leads.
If the grid is made to resonate higher (or the screen to resonate lower),
self-neutralization occurs since the screen is capacitive in respect to
the grid producing DEGENERATION. This is easily accomplished by using
a 500 pf bypass capacitor to raise the resonant frequency of the grid.

A small inductor (3-turns #12 3/8" dia. in parallel with a 100 ohm 2 watt resistor) in series with the screen shifts its natural resonance point below that of the grid, resulting in NEUTRALIZATION.

I know you only asked "what time it was, and I have showed you how to build a watch" but I thought the followers of this thread might like an insight on how innovative hams can get armed with a little test gear and a lot of "gray-matter"!!

(((73))) to all...happy holidays...

I have used laser transparency stock to make pcbs, but with limited success. While it is much cheaper, it requires that you carefully peel away the plastic after it has cooled from ironing on. The toner sometimes adhears to the stock better than the copper and pulls away with it. I haven't experimented with too many brands/types - some may be better than others. _Woody_

Here is one you missed...

You are trying to promote a software
program, that has very little value, at a
tremendous price.

There are better freeware programs. In particular
the Easytrax program which I am sure you are aware of.
It has a block feature, easily understood, that permits
making your own symbols for import.

That you can comm with hams better than the printed
word catches my attention. 1 of perhaps 1000, perhaps, has
any need for a drawing program. PCBoard layouts come with
the construction articles.

Your concern should be directed at producing symbols for the Easytrax
program. THAT would provide proof you are taking hams concerns at heart.

I find no fault in your desire to make a few bucks or a living thru
expertise or business savvy.

The deal on the CC software ain't no deal.

Carl

Now tell me how do you get over $700 discount on that program?
Details OK. I got time.
I think tremendous profits are were or will be made with deals like that
Support? 70% of the program cost for support!
30% for all other expenses... Come onnnn. Did you not think about that
70% in your deal with them?

CirCad is $50 program at best.
Perhaps my copy was not shareware. It was on a shareware CD-ROM
I believe. No matter. The learning curve was too steep compared to
Easytrax which felt like a slight grade.

Yesterdays programs fall by the way fast when compared to more modern ones like DraftChoice - $99. We require a cosmeticly (?) appealing screen nowadays.
If the CC program you are pushing has a nice windows look then perhaps it is
worth $60- $100. You must compare your old CC with the old freeware Easytrax though and when you do the deal on CC ain't no deal.

Hi Pete,

I covered this early on at the very beginning of this thread. The postings have probably expired by now.

The choices are a series resonant supressor path ro ground, or a parallel resonant suppressor path in seriies wth the connection to the low VHF Z tuning capacitor.

There are a few commercial amplifiers that use just such a suppressor.

As to your comments on resistors, the AL-1200 uses a 100 ohm metal film inductive resistor in series with a small siver mica capacitor that series resonates the resistor at the VHF self-oscillation frequency of 100 MHz. The capacitor reduces ten meter current through the suppressor resistor, and increases VHF current through the resistor.

PA's use different methods of suppression depending on the requirements.

ï¿½ I'm not sure that resonance would help resist the flow of VHF current.

>I know it
> would require an additional capacitor -- but I was wondering if this
> wouldn't solve a few problems. First the coil size could be reduced,
> limiting losses at 28 MHz.

ï¿½ The added loss at 28MHz from a low Q suppressor is about 1%. One would need a Bird digital wattmeter to see such a difference. Much smoke has been raised about the deleterious effects of low Q suppressors on 10m harmonic suppression. I have not observed this to be the case. So far, none of my 4500+ customers have reported such a thing. I do not see how it is possible to design a VHF suppressor that does not have some loss at 28MHz.

>Secondly, there would
> be little doubt that most of the VHF currents are flowing through the
> resistor.

ï¿½ As the inductance of Ls is reduced, more current flows through Ls and less current flows through Rs. (see 3/89 QST magazine)

> Another factor I have not seen discussed is how the suppressor

ï¿½ True. Some are more imperfect than others. When Wes Stewart reports his measurements on the resistors we use in the suppressor retrofit kits, we will know for sure. // Cesiwid Co. is supposedly sending me some samples of 100 ohm 20w resistors which have under ten nanoHenry L.

> The most interesting "suppressors" I have seen were used by Hallicrafters
> in an AB1 amp using a pair of 4CX350 tubes. They used wire wound

>
ï¿½ The idea is interesting. However, if the Ls part of the VHF suppressor

is a wire wound resistor, then why not connect a lower-L MOF resistor in parallel with it to enhance the desired stagger-tuning effect? This would increase series-R, and that would decrease the parallel equivalent VHF load R presented to the anode, which in turn would decrease the VHF voltage gain, thereby increasing VHF stability.

Varistors are not too stable with temperature and are not as "sharp" as
zeners. Also, they are not designed for constant dissipation and too much
will cause them to violently ignite.

If you want to play, try some of the older gas regulator tubes (e.g., OA4).
They used to work well, but I would add high value parallel resistors if
making a string of them.

My company has several trimble RTK GPS receivers and I have replaced some of the RG214 antenna cables with RG8X. The antenna connector is an "N" and the receiver end is a single pin LEMO. The EZ "N" from the wireman works ok with the adaptor sleeve for RG59. The EZ N has 2 seals when it screws together and it seems splash proof. I use scotch #23 rubber tape where the coax enters the connector. We also use 470 Mhz RF modems to transmit GPS corrections. The RF connectors on the modems are BNC type and the BNC connectors sold by the wireman for RG8X work good. RG8X is about the same OD as RG59 coax. I used the 75 ohm BNC connectors on the RG8X before I knew the wireman sold the BNC connectors for RG8X.
The RG8X from the wireman is nice stuff compared to the RADIO SHACK crap. The wireman advertises in the ham mags. Very good prices and delivery.

Hi.

I have an older 286 computer that doesn't work anymore. It's
a non-standard case, so I can't put a new motherboard in it.

Since the power supply puts out many amps at 12v on this
particular one... Could I use it to power a mobile radio?

I realize I would have to apply the "power-good" signal (either
ground it or raise it, don't remember which) to get the supply
to work.. (at least that's how I remember it working, haven't
played with computer power supply in a while)

Would it be stable with no load on the 5v side? Could I hook a
big transistor to the 5v size (to ground) to let it see a little
load?

If anyone has done this, I'd appreciate any pointers!

Thanks,
Garry

You can check out a TNC, and operate quite well with the windows
terminal program. It's simple and direct. After you have verified that
the TNC is talking to the computer, try the more sophisticated
programs. Most of the time, a new user does not have the computer baud
rate set to match the TNC, and everything is garbage. Try several
rates, starting with 1200 baud and hit the * (asterisk) several times to
set the autobaud.
Lots of luck ... KB4EG Ron

3976. FS: CONVERSION MANUALS Vol.'s 1,2,3 & CQ TECH SERIES

Newsgroup: rec.radio.amateur.homebrew

>for use at 144 MHz, 1kw cw? Thanks.

At that power level and frequency, I'd go with a double stub tuner made from 3 1/8th inch rigid line. It's a little big, but the Q is high and it'll handle the power. In theory at least, if not in practice, a double stub tuner can match any impedance to any impedance. In practice things get hinky if you go to extreme values.

The two stubs are easy to fabricate, and if they must be adjustable, you can do it mechanically like a notch cavity. In fact you could just use a couple of notch cavities for the stubs if their adjustment range is sufficient. The center trombone section is a little tricky to fabricate. You have to use copper tubing sizes that will nest inside each other for a slip fit for both the outer and inner conductors. A bit of finger stock soldered around the ends of the larger tubes will give good contact. But if the span of adjustment you need is small, you can use a single rigid piece of approximately the correct length and make up the difference in the stubs.

3980. O'scope - Trigger level/Var Sweep

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-15 00:00:00 UTC
From: mhorowit@erols.com
Message-ID: <591nvc$bek@boursy.news.erols.com>
Source record: 99591

Folks -

I can stop a pulse from moving across my scope screen by playing with either the Trigger level or the Variable Sweep; the former seems to lock in more firmer; This is a dual sweep scope, so I've noticed I can display two "in sync" pulses as if they were not in sync, so it's possible to get an erronerous reading. What's the smart way to use these two controls?(the Hold Offest is off)
Thanks, Mike

3982. WTB: Old SB-xxx chassis for homebrew project

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-15 00:00:00 UTC
From: gekko95@ix.netcom.com
Message-ID: <58vj6n$cj7@sjx-ixn8.ix.netcom.com>
Source record: 99669
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.swap,rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Hi! I just bought an old SB-102 chassis with all of the parts removed for $15 to use as a homebrew project chassis. I plan to repaint, and cover the faceplace with a new thin sheet of aluminum for my new rig to live in. (2 stage, 30 watt all band CW rig with built-in VFO)

Well, I need another and possibly 2 more - one for a matching receiver I'm planning, and another for a small amplifier.

So I am looking for ANY SB-xxx chassis, completely stripped of parts or not - don't care what the model was - even could maybe use smaller boxes, like old SB-610 scopes or speaker boxes, or whatever. Again, I am after the boxes and the innards are not important (although if any parts still remain, they would be put away for future homebrew)

Cheap is kind of important, though. That's why I am specifying no parts and looks are unimportant, as long as no dents or cutouts that would be tough to paint over. $10 to $20 is the range I was thinking.

email to Dave gekko95@ix.netcom.com

Thanks to anyone who replies!

I just got a used TNC and I assume it is fine. However, I am having trouble getting the computer to talk to it...I have an IBM PC and am using BITCOM...I tried everything but no luck...Does anyone know where I can find another (simpler) communications program? Bitcom is one of those extremely complicated programs intended to frighten everyone away from their computer...I have the old 360K disk drives as well...A copy of Pakratt-88 might be what I am looking for, or anything that anyone is using successfully would be appreciated...Thanks KB6GK

Thanks Tom.

I can sense your resolve in ending this thread.

Let me say I have followed it with anticipation. Everyone helped me
understand
the ol' amps a lot better. The complete discussion have been archived and
I will get the data and keep it for future reference.

Although the thread was started with a degree of animosity and not
intended to be of great value, it most certainly has been to me. Rich
should be thanked for his
presence to keep the thread alive. You too. Thanks Rich...and others who
made technical comments.

Thanks again.....

Carl

The only thing I could assume Hallicrafters was doing is that by some
remote chance the resistor windings were near series resonance at the
desired frequency. In that case, whatever VHF energy that did not pass
through the
inductor would be dumped into the resistive component of the power
resistor. Seems like a long shot to me!

3992. Digital Freq readout for QRP rigs

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-15 00:00:00 UTC
From: richardh@iinet.net.au
Message-ID: <590cq2$hh3@opera.iinet.net.au>
Source record: 99679

I am designing a freq counter based on the PIC 1 GHz counter (See web page) for QRP/other rigs which do not have digital readout
Planned features:

4 User programmable offsets to 10 Hz resolution. These can be selected via 2 I/O pins along with a user programmable message (eg "USB" etc) These are calculated in software (ie not a 10 turn pot/ADC system which I presume would drift somewhat)

Basic counter resolution around 10 Hz

Bandwidth around 40 MHz

LCD readout

High impedance input so as not to load the LO too much

Simple/small physical size (around 3 by 5 inches for the board)

I will be marketing this at about $90 US for the kit

I would appreciate any ideas re features/cost etc

Thanks

Richard Hosking

Tom told us that there was virtually no VHF current in Ls. However, when
Tom provided me with a problem that he presumed would prove himself right
and prove me wrong, it revealed that there was actually more VHF current
in Ls than there was in Rs. // Tom originally claimed that that there
was no difference in VHF Q when Ls was made from resistance wire, and that
a serious decrease in HF Q would be effected. Now Tom wants us to believe
that resistance wire encourages VHF oscillation. Does it make sense that
the resistance of a conductor DECREASES with an increase in frequency?

The first QST magazine article about intermittent VHF parasitic
oscillations was published in October 1988. During the next ten months I
received around 1400 letters and telephone calls from people who said that
they had experienced the problem. QST appeared to welcome the followup
article "Parasitics Revisited" in the September and October 1990 issues
of QST. However, shortly after my article "The Nearly Perfect Amplifier"
was published in the Jan., 1994 issue, QST Editor Mark Wilson sent word
to me that via Al Brogdon, that he was getting pressure from advertisers.
Paul Pagel, the editor of the Technical Correspondence column, was
mysteriously pulled off of his column for the Sept. 1994 issue---wherein
Mr. Tpm Rauch recognized himself as one of the "recognized amplifier
experts", and claimed that I did not know what I was talking about since
virtually no VHF current flows in a VHF suppressor's inductor.
...........Nice going, Mark.

One of the ARRL Directors wrote a letter to the ARRL President about the
Sept. 1994 Technical Correspondence column. He said:

"After we both lost expensive 8877s, I installed Measures parasitic suppression kit in both amplifiers. I am happy to say that the problem has never recurred to either of us. For Telewski to categorically state that it is only the external circuitry is at fault is nonsense. The loop which causes the oscillation includes the tube itself as well as all surrounding external circuitry." ... ... "All in all, I feel the September 1994 rebuttal was vindictive. I hope that there was not a 'secret agenda" underlying the rebuttal. In the interest of journalistic fairness, I believe that Najork's request for an apology is in order. I also believe that Measures' rebuttal should be printed in QST."

The complete text of this letter is currently available at:
<http://www.vcnet.com/measures/> see link to 'rebuttal postscript'.

> I have no more time for arguments. ...snip...

Mr. Rauch told us "that Mr. Miklos was indeed R+D engineering manager for Varian". I telephoned the Personnel Department at Varian-Eimac's Salt Lake City plant. They told me that Mr. Joseph 'Buzz' Miklos' title was "Engineer B". They assured me that Mr. Miklos was not the R and D Engineering Manager. I posted the information here.

RE: "I have no more time for arguements..." :
Translation: Having been caught adjusting the truth about Mr. Miklos' position at Varian, Mr Rauch seems to have abandoned the very debate that he desired since 1990.

3994. Need help -Eico 955

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-15 00:00:00 UTC
From: screamer@li.net
Message-ID: <32b7f064.137618184@newshost.li.net>
Source record: 99681

I hope someone can answer this. I have an Eico 955, in circuit capacitance tester. The unit is missing the test lead. I understand the cable used for this lead is most important for an accurate reading. Does anyone have a clue as to what the origional test cables designation was?

Any help will be most appreciated.

Please reply via e-mail, since I don't frequent this group.

Dave,

There are true 75-ohm BNC's, an example is the Kings male BNC that fits Belden 1694A 75-ohm serial digital video cable. 1694A cable passes 270-megabit/sec serial data, and impedance at all connections must be carefully controlled. 1694A cable is about 3/8" O/D. I forget the Kings part number right now but can look it up. You can get true 75-ohm BNC's at Pacific Radio, Hollywood, CA, and from H.L. Dalis Co. on Long Island.

Rather than try to tell the 50 from 75 ohm connectors by appearance, I just look at the part number stamped on the outer edge of the coupling ring.

At work, we're rebuilding TV studios, converting them to digital, and use these BNC's by the thousands.

For many years Neon bulbs were used as a reference voltage source for high-voltage power supplies. If your current levels are consistent, go to Radio Shack, stack up a few bulbs (70 to 90 volts per bulb) and get the 'scope back up. Make sure the current is properly limited!

Hope this is of help.

Since the impedance of a coaxial system is related to the log of the ratio of conductor diameters, the center pin of a 75 ohm BNC is smaller than a 50 Ohm version.

Usually, the 75-ohm variety comes with a machined groove around the circumference to mark it as a 75 piece.

Since center pins are larger, don't plug 50's into 75's.

Clear as mud?

3999. WTB: Old Heat SB-xxx chassis for homebrew projects

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-15 00:00:00 UTC
From: gekko95@ix.netcom.com
Message-ID: <591b63$npi@dfw-ixnews2.ix.netcom.com>
Source record: 99686
Cross-posted to: rec.radio.swap,rec.radio.amateur.equipment,rec.radio.amateur.boatanchors,rec.radio.amateur.homebrew

Hi! I just bought an old SB-102 chassis with all of the parts removed for $15 to use as a homebrew project chassis. I plan to repaint, and cover the faceplace with a new thin sheet of aluminum for my new rig to live in. (2 stage, 30 watt all band CW rig with built-in VFO)

Well, I need another and possibly 2 more - one for a matching receiver I'm planning, and another for a small amplifier.

So I am looking for ANY SB-xxx chassis, completely stripped of parts or not - don't care what the model was - even could maybe use smaller boxes, like old SB-610 scopes or speaker boxes, or whatever. Again, I am after the boxes and the innards are not important (although if any parts still remain, they would be put away for future homebrew)

Cheap is kind of important, though. That's why I am specifying no parts and looks are unimportant, as long as no dents or cutouts that would be tough to paint over. $10 to $20 is the range I was thinking.

email to Dave gekko95@ix.netcom.com

Thanks to anyone who replies!

Ok, I also have a question or two.
Maybe I missed something about how to test parasitics.

When building my 4-1000A pair linear, I used a variac to increase
the plate voltage cautiously looking for a feared parasitic.
Since the gain of the tube increases with plate voltage,
it happened, that I only got a parasitic when at the target
plate voltage of 6000 volts.

My experience was that for that instant of the parasitic,
I couldn't do much of anything, much less measure it's frequency.
I had a inline fuse in the B+ line, which exploded, the force of
the concussion of the explosion breaking things up to several feet away.
How do you folks measure the frequency of your parasitics when they explode
with such violent force?

What measures are used to test for parasitics in a less
destructive fashion?

>I have a question. Probably shouldn't ask it, but I am going to
>anyways. What would happen if the parasitic suppressor was made

Not necessarily. If the unloaded Q of the varactor is much higher
than the unloaded Q of the inductor, the inductor will be the
limiting factor, and there will be no advantage to replacing the
varactor with a variable capacitor of even higher Q. [Phase
noise is inversely proportional to Q]. The best ferrite
inductors, to my knowledge, top out at an unloaded Q of about
500. Varactors with Q's of many thousands are commonly
available. Of course, good engineering practice must be followed
regarding tuning voltage management to avoid externally induced
noise from being generated in the varactor. Another tip is to
always take the output directly from the tank, and use a low
phase noise buffer amplifier following the oscillator.

Hi Rich--

As far as I have been able to discern from this thread--and from past media wars--is that there is no conspiricy here. I suspect Dick Erhorn, Tom Rauch, Dick Frey, and those various "demon" engineers at Eimac and elsewhere who are "attempting to hide the truth from the amateur public" are nothing more than a wishful figment of your imagination. The fact is, you have written extensively--and you currently have a web page--where you make money selling a product that is based upon the premise that others in the industry are stupid and incompetent. That's a pretty big burden of proof to carry, Rich. How's it working out??

Hi Richard,

I'm afraid your statement about Mr. Miklos is not correct. Since it has so
little to do with parasitics, I was simply going to ignore it. It does
little good for us to argue about what you "heard" or what I head, it
means nothing to anyone else.

Two things about your claim does not make sense.

First, the personel department at Varian would not release employment
information to some voice over the phone without a signed release by that
employee.

Second, I've known Mr. Miklos and the guys at Varian for many years now.
Mr. Miklos was indeed manager of power grid R+D at the Salt Lake plant
from 1989 throgh 1992. In 1992 he left to work at a division of Siemens.

Your statement is not correct, plus I have serious doubts the personel
department would release employee history to the self-appointed
spokesperson of Varian 500 watt 8877 grids.

Who at Varian gave you that information? Did you "record" that
conversation?

Back to parasitic's and nichrome. You seem to not understand the concept
of impedance. Do you think a thin nichrome wire has the same series
impedance as a thick copper wire or strap? It has higher impedance Rich,
so it raise the series equivalent anode impedance.

Here's something for everyone to think about, and something Rich needs to
answer.
Richard claims the nichrome greatly de-Q's the anode at VHF. He also

claims the tuning capacitor and bandswitch can arc from VHF energy from parasitic.

1.) In order for the bandswitch or capacitor to arc, they MUST have very high VHF impedances.

2.) If anything is placed between the anode and that high impedance, it will have little effect on Q unless the added impedance is very high and very resistive.

3.) If the added impedance (ie the nichrome) is very high and resistive, it can only RAISE the anode's load impedance at VHF and increase VHF gain.

In order for the nichrome (or ANY suppressor in series from the tube to the tank) to work, the tank must present a very low VHF impedance to the suppressor. If the tank looks like a very low VHF impedance, the tank can't develop enough voltage to arc at VHF.

Once again, Richard seems to argue against Richard. Is the tank a high VHF impedance at the tuning capacitor, or a low one? It can't be both.

Is the nichrome wires resistivity and reactance higher than a thick round conductor or wide strap, or lower? It can't be both.

73 Tom

4006. Specs. on MECA bidirectional coupler 700-M042?

> hide the problem - fix the antenna.

Quite correct, match the antenna if possible.

It rather depends on if you need a matching unit or a tuning unit and what it is for. E.g resonating a mobile whip (not with 1kW). turning a 1.5:1 VSWR to a 1:1 VSWR to protect some poor power transistors, for example when operating a high Q 144 MHz antenna at 147 MHz. Matching an open wire feed system to 50 ohms, or even tuning up the HF wire dipole that is all you can put up owing to antenna restrictions.

ATUs, or more corectly AMUs are used frequently on VHF. My 4m antenna has a built in ATU - called a Gamma Match. My valve amplifier also has a device to tune the 3k ohm output to the 50ohm coax. Our box of 4 yagis (co-ax fed for portable use Ian) has a 1/4 wave line matching unit to transform 12.5 ohms to 50 ohms.

Therefore, to answer the question. Assuming you are trying to match a 50 ohm line to a near resonant antenna, you can use a pi or pi-L network just like an HF atu, except the inductor will just be a length of thick copper - length cut to suit. The capacitors will be low loss air spaced flappers - like used in valve amplifiers. Calculate the value of L and C required, cut L to length and make the Cs adjustable. REsonate and match. Place as close to antenna as possible.

At higher frequencies you can use a stub tuner, but these are a bit big on 144 MHz.

It is more a matter of where you put the ATU than if you use one.

4009. Short Wave AM transmitter wanted.

>

I've gone through considerable trouble to rid the lab of broken
75 Ohm sockets, and I never cease to harass newbies here to take
good care of connectors.

In my opinion, the people who designed the 75 and 50 Ohm BNCs to
be so closely alike that only specialists can tell them apart
deserve to be fried to a crisp.

And they did it again with N-connectors, and C, and probably some
others I haven't encountered yet.

Is it laziness, unwillingness to design a *different* interface?
Is it a conspiracy? Will they ever learn?

(in reply to something Wes Stewart wrote)

: None of my British handbooks mentions NBS, and neither did US sources
: such as the 1950 ARRL Handbook or the 1959/60 and 1977/78 editions of
: the Handbook of Chemistry and Physics.

: I finally found it in the 1941 edition of Machinery's Handbook:

: "This Standard Wire Gage (also known as the Imperial Wire Gage and the
: English Legal Standard) is used in England for all wires. The
: abbreviation S.W.G. is sometimes used for Standard Wire Gage, also the
: abbreviation N.B.S. for New British Standard Wire Gage. This gage was
: legalized in Great Britain in 1883."

: It seems that Reference Data for Radio Engineers uses wire tables that
: date back to the days when NBS really was "New"!

The newer 7th edition, dated 1986, and now called "Reference Data for Engineers," has a table, "Courtesy Whitehead Metal Products Co., Inc.," which is a comparison of various gauge standards. It lists "AWG B&S," "Birmingham or Stubs BWG," "Wash. & Moen W&M," "British Standard NBS SWG," "London or Old English," "United States Standard US," and "American Standard Preferred Thickness." (The last one isn't really a gauge number standard...) I'm sure there are others. I would hope the part of the world that's been smart enough to go metric has also converted to simple metric diameters and thicknesses in place of gauge numbers, but I guess old habits die hard. Thank goodness US manufacturers are getting metricized, even though our kitchens and roadways are still miles and ounces and tablespoons...

Untruthfulness is probably the surest way to loose public support---and the fastest way to ruin one's chances of winning a public debate.

It's unfortunate that Mr. Rauch bailed out, Phil. This morning I got an e-mail from Rick KC0HH, who has had two bandswitches mysteriously burn up in his Ameritron AL-80A amplifier. Rick said: " I am really tired of spending all day Sunday re-installing a band switch...."

Hello, Rick
I never claimed that there was a conspiracy. I presented the evidence I have. The reader decides.

> I suspect Dick Erhorn,
> Tom Rauch, Dick Frey, and those various "demon" engineers at Eimac.

Where did you see the term 'demon engineers'?. I credited Eimac engineers with apparently pointing me in the right direction back in February 1986. // To the best of my knowledge, Dick Erhorn and Tom Rauch have never inspected a kaput tube for the presence of gold-sputtering to see if Mr. Foote and I are right or if we are wrong. Mr. Rauch said he had some kaput 3CX800A7s whose gold grid-plating he claimed had evaporated from 150mA (<5w) of HF grid current. I offered to dissect, photograph, and post the pictures of the insides of one of these3CX800A7s on my web site for all to see. Mr. Rauch stonewalled me.

> ......and elsewhere who are "attempting to hide the truth from the amateur public"

> you have written extensively--and you currently have a web page--where you
> make money selling a product that is based upon the premise that others in
> the industry are stupid and incompetent. That's a pretty big burden of
> proof to carry, Rich.

Are some amplifier manufacturers incompetent? Consider the cut-and-dry issue of filament voltage. The rated filament voltage for a 3-500Z is 4.75v to 5.25v. Eimac says that the emissive life of a thoriated tungsten filament/cathode varies as E1/E2.^23.4. If you bought a commercial 3-500Z amplifier, Rick, and you subsequently discovered that the filament voltage at pins one and five on the tube sockets was 5.95v with an electric-mains voltage of 240v, would you conclude that the amplifier was competently-engineered? (such fil-v reduces life to under 1 percent of normal) // This is not a figment of anyone's imagination, Rick. The amplifier's manufacturer is Henry Radio Co. Other manufacturers have the same problem. Do you think its okay to run 15V on a 3CX800A7 filament?

Rick: Do you think 48A of filament inrush current is ok for a 3-500Z?

The low VHF Q suppressor retrofit kit mail order business was not my idea. It was suggested by people who apparently had parasitic oscillations damage their amplifiers. From its beginning in December 1988, I operated the business as non profit. The only person who makes any money is my helper who runs the business.
>
How's it working out??

After selling 4500+ low VHF Q parasitic suppressor retrofit kits, it appears that the market is beginning to saturate. There doesn't to be many hams these days who know how to solder, Rick

Is the ARRL independant of advertisers? The ARRL lab technician who tested the AL-1200 amplifier told me that he observed what appeared to be intermittent VHF parasitic-related arcing during lab testing. This information did not appear in the QST product review.

Do you feel that Mr. Rauch's prevarication about Eimac/Salt Lake City. ex-employee Mr. Miklos was justified?

A PHONE SYSTEM FOR HOME OR OFFICE.
SCHEMATICS AND SOURCE CODE INCLUDED.
DELIVERED TO YOU *- WORKING -* RIGHT OUT OF THE BOX.

http://www.PhoneSwitch.com
sales@PhoneSwitch.com

Greetings, This is a repost and is crossposted. Many thanks to the person who told me about crossposting, I can see how its very usefull.

If you have been given the responsibility to design a hardware product which interfaces to a telephone set or a telephone line or you are just interested in the intricacies of telephone call processing based on a state machine then the Small Telephone Switch Evaluation Kit is for you.

The EVKIT includes a working PCB, schematics and source code written in C.

You can make calls between extentions or to the outside lines. Incomming calls can also be transfered between extentions. Its a complete PBX that you can change the software on! Even add new hardware features...

Begin of EVKIT overview:

The sx38 product is a complete small modularly expandable open architecture private branch exchange on a 12" by 12" circuit board and is delivered partially assembled with a PC compatible 65W power supply.

The sx38 switch can provide complete standalone service in remote applications.

Complete schematics and source code (8051 written in C, compatible with popular compilers) are provided to facilitate development of industry standard peripherals, interfaces, software and companion switching modules.

The basic printed circuit board has 8 subscriber line interfaces and 3 central office line interfaces. 2 of the slics and 1 of the co interfaces are delivered pre-assembled, working and tested.

12 speech paths are provided to support non-blocked operation and support multiple conference calls in progress at the same time.

All of the ports have the same terminating impedance when measured from the switch matrix allowing any port to be connected to any other port.

One board provides a complete system, all the necessary common control and signaling components to set up multiple conversations at one time are included.

Basic and flexible, the software is modular by nature allowing complete software control to create sophisticated communications products.

The evaluation kit is $375 and is provided with a power supply which is UL registered. Two of the eight slics and one of the three co interfaces are already assembled. When you receive the board you will be able to lift either extension phone and receive dial tone, be able to make intercom calls which ring standard phones, make calls external to the system by dialing 9, receive calls from the outside and transfer the calls to another extension and answer any ringing phone by dialing 9. The evaluation kit works when you receive it. You can also expand the evaluation kit by adding easy to purchase components and simply soldering them to the board following the pattern of the already assembled circuits.

Feature Overview:
8 station 3 trunk, expandable to 16 station 6 trunk. (expansion board is $160 partially assembled).
2 DTMF Senders (one is provided in the EVKIT)
2 DTMF Receivers (one is provided in the EVKIT)
2 imprecise call progress receivers (one is provided in the EVKIT)
2 dial tone generators
90vac 20hz Bell Ringing Invertor
SLIC Supervision Generator (forces answering machines to hang up)
SLIC Ring trip detect (detects offhook during application of ringing signal)
All ports can add gain to the call.
SLIC can transmit audio during on-hook. (Slic can send audio, like caller id, to extensions)
CO can receive audio on-hook (caller id can be decoded by a central, shared, CID decoder)
2 expansion connectors with CPU bus and audio channels.
Full Duplex Serial Port (300,1200,9600 bps 8-N-1)
Conference Matrix for conference calls. (Any time three ports need to be on the same call.)
8051 CPU, 64KROM, 8KRAM

Suggested Applications with provided software:
+Small Telephone System for Home or Small Business.
+Personalized Ringing Pattern Decoder for fax machine or modem.
+Modem Pool controller. You cant barge in on a conversation in

progress.
+Any place one phone needs to call another.
+Any place one, two or three telephone lines need to be shared in a convenient non intrusive manner.

Applications you might develop by modifying the software and interfacing to the hardware:
+SEAMLESS integration of internet phone software/sound blaster card to home or office phone system. Imagine picking up a standard phone and dialing a intercom call around the world over the internet phone and reaching another standard phone at the other end. Might even be able to receive calls from the switched network and go back to the switched network.
+Automated and transparent (to the user) intercept and rerouting of voice calls to private networks or common carriers. (1+ to 10XXX+ as an example).

Remember the schematics and source code are included which makes modification, expansion and integration easier.

Important note: This system is based on technology I presented in a article in Circuit Cellar- The Computer Applications Journal. The EVKIT is MUCH IMPROVED over the circuits presented in the article. If you are looking for something which is COST EFFECTIVE and CHEAP then the EVKIT is probably not for you. The EVKIT is comparable to what other companies are offering except the SCHEMATICS and SOURCE CODE are provided with each unit. No other telephone switch manufacturer does this.

John,
You said that you tried RIT die for one hour. Did you use any heat?
I've never tried to die the type of plastic you refer to, but I have
died several peices of nylon with excellent results. I found thaif you
bring the die to almost a boil, it only takes about 15 minutes to get
good color. You need to maintain the high temp for the duration of the
soaking. I hope this helps.

I have collected together some references to magazine articles about WWVB/WWV/LORAN-C/LF/VLF radio receiver design and construction. I put the list up on my web site. I also put some digital clock stuff up that I stumbled across while looking through old magazines. I would be interested in any other references that relate to this stuff.

I would also be interested in leads to kits for receivers of this type.

Thanks Much.

>I asked Marvin why he felt he needed a kit. He said that the AL-1500 had
an >intermittent VHF oscillation he could see on a spectrum analyzer, as
well as see on >Tektronix 454 oscilloscope.

Richard, I just got off the phone with Marvin Born.

Marvin said he clearly told you he measured the parasitic in a 3CX3000
amplifier, NOT in the "1500". Not only that, Marvin said the "1500" he is
repairing uses a pair of tubes. It has a different tube chassis and
transformer (more voltage) than the real AL-1500.

As we talked, things started to click. I asked him if the owner of the PA
was Jim Hurt, KC8MK. Indeed it was.

KC8MK was a saleman that used to call on Prime Instruments, and operated
160 meter contests at my South Amherst Ohio QTH. I gave Jim a scrap
prototype chassis (less most major components) in 1985. He wanted to build
a pair of 8877's and had no sheet metal equipment. That amp got him
started on his project.

Rest assured, the ONLY thing in that PA that is factory is basically the
cabinet!!!! Even the tube chassis and the transformers are non-factory.

Marvin insists you VERY clearly knew the 1500 was heavily modified without
the best craftmanship with two 8877 tubes in parallel. He also was
absolutely sure you knew the parasitics were measured on a 3CX3000, NOT on
this PA. (It isn't even running yet)

Richard, it would be better if you stuck to technical issues.

If people read back and count the times you've slammed others, including people like Dick Erhorn, Mark Wilson, Tom Rauch, Fred Telewski, Reid Brandon, Bill Clemow, John Fakan, Steven Katz, Buzz Miklos, and Bill Orr, they might just think you don't trust anyone. The list also includes organizations like the ARRL, ETO, Henry, Kenwood, Ten-Tec, Varian, NASA, and even Ford!

Ford, NASA, Nixon... they all have nothing to do with parasitics. Neither does your dream conversation with Marvin about a measurement he never even made. AL-1500 indeed, and you KNEW better!

And you accuse me of deception and smoke? Check the mirror, Rich.

Tom

hi gary
i am using an old pwr-supply for driving lamps, motors, etc.
the 'power-good'-signal is an output i think; he tell's the watchdog of the computer to protect the memory from writing if power fail's. this is 'cause the cpu makes bullshit when power is not stable.
i never had problem's with unused power-lines, even if you have, don't use a transistor, use a simple resistor (try a 50R, 1W).

BUT: The output of a computer-power-supply (a switching-power-supply) is extremly noisy!!!
this is why i use it for lamps etc, remember that computer work's digital; if you use the supply for analog gear, you will have problem's.

on the other side, there exist's switching-power-supply's for ham-radio too. they work with frequencies higher than you can hear and they have much filtering-parts.

so - if you want use your power-supply - no problem, but don't be surprised about the 'side-effects'...

have fun...

Quite correct, match the antenna if possible.

It rather depends on if you need a matching unit or a tuning unit and what it is for. E.g resonating a mobile whip (not with 1kW). turning a 1.5:1 VSWR to a 1:1 VSWR to protect some poor power transistors, for example when operating a high Q 144 MHz antenna at 147 MHz. Matching an open wire feed system to 50 ohms, or even tuning up the HF wire dipole that is all you can put up owing to antenna restrictions.

ATUs, or more corectly AMUs are used frequently on VHF. My 4m antenna has a built in ATU - called a Gamma Match. My valve amplifier also has a device to tune the 3k ohm output to the 50ohm coax. Our box of 4 yagis (co-ax fed for portable use Ian) has a 1/4 wave line matching unit to transform 12.5 ohms to 50 ohms.

Therefore, to answer the question. Assuming you are trying to match a 50 ohm line to a near resonant antenna, you can use a pi or pi-L network just like an HF atu, except the inductor will just be a length of thick copper - length cut to suit. The capacitors will be low loss air spaced flappers - like used in valve amplifiers. Calculate the value of L and C required, cut L to length and make the Cs adjustable. REsonate and match. Place as close to antenna as possible.

At higher frequencies you can use a stub tuner, but these are a bit big on 144 MHz.

It is more a matter of where you put the ATU than if you use one.

Hi Rich--

As far as I have been able to discern from this thread--and from past media wars--is that there is no conspiricy here. I suspect Dick Erhorn, Tom Rauch, Dick Frey, and those various "demon" engineers at Eimac and elsewhere who are "attempting to hide the truth from the amateur public" are nothing more than a wishful figment of your imagination. The fact is, you have written extensively--and you currently have a web page--where you make money selling a product that is based upon the premise that others in the industry are stupid and incompetent. That's a pretty big burden of proof to carry, Rich. How's it working out??

Hi Richard,

I'm afraid your statement about Mr. Miklos is not correct. Since it has so little to do with parasitics, I was simply going to ignore it. It does little good for us to argue about what you "heard" or what I head, it means nothing to anyone else.

Two things about your claim does not make sense.

First, the personel department at Varian would not release employment information to some voice over the phone without a signed release by that employee.

Second, I've known Mr. Miklos and the guys at Varian for many years now. Mr. Miklos was indeed manager of power grid R+D at the Salt Lake plant from 1989 throgh 1992. In 1992 he left to work at a division of Siemens.

Your statement is not correct, plus I have serious doubts the personel department would release employee history to the self-appointed spokesperson of Varian 500 watt 8877 grids.

Who at Varian gave you that information? Did you "record" that
conversation?

Back to parasitic's and nichrome. You seem to not understand the concept
of impedance. Do you think a thin nichrome wire has the same series
impedance as a thick copper wire or strap? It has higher impedance Rich,
so it raise the series equivalent anode impedance.

Here's something for everyone to think about, and something Rich needs to
answer.
Richard claims the nichrome greatly de-Q's the anode at VHF. He also
claims the tuning capacitor and bandswitch can arc from VHF energy from
parasitic.

1.) In order for the bandswitch or capacitor to arc, they MUST have very
high VHF impedances.

2.) If anything is placed between the anode and that high impedance, it
will have little effect on Q unless the added impedance is very high and
very resistive.

3.) If the added impedance (ie the nichrome) is very high and resistive,
it can only RAISE the anode's load impedance at VHF and increase VHF gain.

In order for the nichrome (or ANY suppressor in series from the tube to
the tank) to work, the tank must present a very low VHF impedance to the
suppressor. If the tank looks like a very low VHF impedance, the tank
can't develop enough voltage to arc at VHF.

Once again, Richard seems to argue against Richard. Is the tank a high VHF
impedance at the tuning capacitor, or a low one? It can't be both.

Is the nichrome wires resistivity and reactance higher than a thick round
conductor or wide strap, or lower? It can't be both.

73 Tom

It is unfortunate that W8JI's article 19961213151600 that 2X4 is
responding to above was pulled from this news group before I got
to read it! Perhaps 2X4 will be kind enough to repost it so we can
all "sense [W8JI's] resolve in ending this thread." It is like
reading a novel only to find out someone tore out the last page!

Thanks,

Subject: O'scope - Trigger level/Var Sweep

Folks -

I can stop a pulse from moving across my scope screen by playing
with either the Trigger level or the Variable Sweep; the former seems
to lock in more firmer; This is a dual sweep scope, so I've noticed I
can display two "in sync" pulses as if they were not in sync, so it's
possible to get an erronerous reading. What's the smart way to use
these two controls?(the Hold Offest is off)
Thanks, Mike

> Ron

You can check out a TNC, and operate quite well with the windows terminal program. It's simple and direct. After you have verified that the TNC is talking to the computer, try the more sophisticated programs. Most of the time, a new user does not have the computer baud rate set to match the TNC, and everything is garbage. Try several rates, starting with 1200 baud and hit the * (asterisk) several times to set the autobaud.
Lots of luck ... KB4EG Ron

THE COMPLETE RF TECHNICIAN'S HANDBOOK

(Published by Howard W. Sams, Inc.)

"The Complete RF Technician's Handbook" is THE book for the radio communication s beginner, student, or experienced technician, and supplies priceless information on not only wireless fundamentals, but also the advanced concepts vital to a successful career in RF communications.

Included are over 400 informative ILLUSTRATIONS and tables

The handbook includes everything a technician needs to know in real-world RF electronics -- from the fundamental concepts to the more advanced explanations of modern ANALOG and DIGITAL RADIO circuits and modulation methods. Furthermore, operational instructions on RF TEST EQUIPMENT, as well as identifying proper and improper signal waveforms, and AM, FM, PM, and SSB theory are included. In addition, transmitter and receiver testing methods and TROUBLESHOOTING TECHNIQUES are solidly covered.

For Further Information Please View The Web Site At:

Hi Rich--

In your last post, you wrote:

"Is the ARRL independant of advertisers? The ARRL lab technician who tested the AL-1200 amplifier told me that he observed what appeared to be intermittent VHF parasitic-related arcing during lab testing. This information did not appear in the QST product review."

The League has reviewed several pieces of my equipment, and I can vouche--first hand--that they will not, under ANY circumstance, withold reporting an anomoly in performance in a review--no matter WHO the vendor is or how much they spend annually on advertising. In fact, even when the observation is misinterpreted by the reviewer or not relevent to normal operation, they'll print it anyway! So I cannot accept your claim as having any credibility whatsoever. Also, I doubt the lab tech would independently arrive at a conclusion that arcing was caused by VHF parsitics--without your suggesting it to him in some way. I talk to these people on a regualr basis, and they are usually very careful not to make presumptions.

Linear amplifiers are not my area of expertise, which is why I have found this thead to be particularly interesting and instructional. The only reason I am intervening at all is because, from time to time, the dialog jumps off a technical track and into Rickie Lake style bickering over who did what and who said what. For me, that type of interchange serves no useful function except to deflect debate away from the real issue at hand. Wouldn't it be better for your VHF parasitic theory to stand or fall on the basis of its technical merit rather than remain muddled up in a mass of foolish charges and counter-charges?

Having registered my vote for sticking to technical issues, I'll get out of the way and let the debate continue.

-- Rick K1BQT

Hi Richard,

You seem to always confuse information to suit your needs.
.
In article <measures-1612961439480001@port10.vcnet.com>,
measures@mail.vcnet.com (R. L. Measures) writes:

> Mr. Rauch said he had some kaput 3CX800A7s whose gold grid-plating he
>claimed had evaporated from 150mA (<5w) of HF grid current. I offered to
>dissect, photograph, and post the pictures of the insides of one of
>these3CX800A7s on my web site for all to see. Mr. Rauch stonewalled
>me.

What would a picture show? The tube was overdriven by HF energy, I know because I over-drove it. I had the grid overload circuit disconnected, and that allowed me to damage the grids. I very plainly explained that.

More important YOU recommend disconnecting electronic grid overload circuits. That suggestion is idiotic.

>amplifier's manufacturer is Henry Radio Co. Other manufacturers have the
>same problem. Do you think its okay to run 15V on a 3CX800A7 filament?

Not all PA designs are perfect, so what does that prove? Do you want people to believe because Henry missed on filament voltage it makes you and expert? How about the AL-1500's that come in with your mods that have 4 volts on the filaments, and the cathodes are stripped? Is it a good idea to tell people to reduce voltage, and not tell them in detail how to measure it and what steps to take? Is it a good idea to tell them to disconnect protection circuits?

> Rick: Do you think 48A of filament inrush current is ok for a 3-500Z?

Name the PA, describe how you measured it. You never describe your methods, you just tell people there is a problem wioth everything built.

In ~~1986, Eimac (Buxx Miklos) did a test on 3-500Z filaments. He strapped 3-500Z's directly to a 5 volt 200 amp transformer and cycled the filaments off and on. In months of testing, they couldn't detect damage on any 3-500Z filaments.

While excessive inrush is a bad idea, the failure mechanism is thermal in nature. It is cause by the repeated rapid heating of the filament. It is accumulated damage, not instantaneous. It is a product of how much overload, the duration of the overload, and the accumulated number of thermal cycles.

A person could never observe the increase in failure due to 48 amperes of short time inrush in a 3-500Z in amateur service. The anode welds would fail, the tube would gas up, a grid wire would break, or something else would likely happen LONG before the filament would open from that small amount of inrush, assuming the inrush was caused by filament resistance delta.

>The low VHF Q suppressor retrofit kit mail order business was not my
>idea. It was suggested by people who apparently had parasitic
>oscillations damage their amplifiers. From its beginning in December
>1988, I operated the business as non profit. The only person who makes
>any money is my helper who runs the business.

Bunk. It feeds your hungry ego as well as you pocket. It is your 15 minutes of fame.

>After selling 4500+ low VHF Q parasitic suppressor retrofit kits, it
>appears that the market is beginning to saturate. There doesn't to be
>many hams these days who know how to solder, Rick

Maybe they found out your claims are false. That usually ruins sales.

>Is the ARRL independant of advertisers? The ARRL lab technician who
>tested the AL-1200 amplifier told me that he observed what appeared to be
>intermittent VHF parasitic-related arcing during lab testing. This
>information did not appear in the QST product review.

Bunk.

When the AL-1200 was tested, the lab people used a triac switched voltage regulator that sampled RMS line voltage. The regulator squared the waveform going into the AL-1200 resulting in extremely poor voltage regulation. No load, the supply was a sine wave, full load, the supply was a square wave.

While Richard fabricates a theory QST is under the thumb of manufacturers, QST refused to corrected their review that indicated low power output and low full load HV due to poor power source regulation. When the PA drive was removed, the regulator would spike up to extreme voltages. They told ME to write a correction and they would print it in technical correspondence. I refused, because it was their mistake...not mine.

Since that review, the ARRL has quit using that regulator.

Independent of that, QST is very honest. They do not cow-tow to any pressure. They occasionally make mistakes or use poor judgement (as they did when they printed your trash), but they don't intentionally lie to members. Your claim is bunk Rich, and you know it.

You invent some pretty wild stories Rich. I wonder how a person sitting in California knows "so much detail" about what happens between individuals in other areas of the world. I wonder how much of what you say is accurate, when you can't the details of a conversation with me correct, or a conversation with Brandon, or a conversation with Marvin Born. I wonder how much is accurate when your theories make ltlle to no sense at all.

You are now completely avoiding technical issues, and totally relying on stories that come only from you. Stories that can't be confirmed, so we just have to take "your word". The Q issue is bunk, several of us have said so. The photon issue is bunk, a physicist from England and others said so. The grid damage issue is bunk, Eimac said so.

You should lighten up on the rest of the world, until your own honesty is in order.
You are your own worst enemy, wasting all your excellent writing ability to promote obviously false claims and make a few bucks off some nichrome.

What a waste of space and time this has been.

73 Tom

4032. Wanted: 10mSSB convertion info for Cobra 134.

: You said that you tried RIT die for one hour. Did you use any heat?
: I've never tried to die the type of plastic you refer to, but I have
: died several peices of nylon with excellent results. I found thaif you
: bring the die to almost a boil, it only takes about 15 minutes to get
: good color. You need to maintain the high temp for the duration of the
: soaking. I hope this helps.

The suggestion on heat with RIT dye is correct. Several hundred
years ago -- when I was in the US Air Force -- I wore those ugly
military issue glasses. (-: The price was right :-) They had
translucent grey frames. Someone told me to bring them to a
near-boil on a pan of water and RIT dye. Luckily black glasses
frames were the fashion choice of the times. It worked Really Well.

(Too much of a boil and the %^#^&%$ lenses fell out. :-)

Nah. The cat's out of the bag, Tom Rauch. You were caught red-handed,
and you are telling another one to cover it up.

> I was simply going to ignore it. It does
> little good for us to argue about what you "heard" or what I head, it
> means nothing to anyone else.

It means C. Tom Rauch, Jr. did not tell the truth. To me, such a
shenanigan means more than 'nothing'.

> Two things about your claim does not make sense.
>
> First, the personel department at Varian would not release employment
> information to some voice over the phone without a signed release by that
> employee.

Yeah, that's what you were banking on, but it didn't work I phoned
Eimac's Salt Lake City division at 801-972-5000. I explained what has
been taking place in this debate. I said that certain claims about Mr.
Miklos were being made in his absence, and that I would like to verify
these claims. We are hardly talking about national defense secrets.

Under normal circumstances, Tom, you might have gotten away with it.
However, there were some unseen factors at work that may have upset your
apple cart.

In my family, there are two pathological liars, so I am familiar with how
such individuals operate. Briefly, EVERYTHING these indivuals say needs
to be investigated. When one lie gets exposed, they often tell another
lie to cover the previous lie, on and on. .

I found out how you lost control of Ameritron to MFJ.

Allen,
do a search for "CB Radio". Look at Left Coast CB abd it's links.
You will find an abundance of info on PLL unlocks. If you know the PLL, I may be able to provide some info for you. Getting the fo's is the easy part....Broadbanding the receive and transmit capabilities requires some time, effort and substitutions. There are "tricks" such as adding more broad varactor diodes in the vco and ssb circuits, paralleling unused sections of IF transformers, changing the value of the synth crystals, etc. Some PLL's and circuit board combos are better than others, and the Cobra usually uses a Uniden board with either a 8719 or 8734 PLL IC.

The best authority is Lou Franklin of CB Cint International. You can contact him at info@cbcintl.com .
He has written variouis volumes of info covering whatever level of info you care to get into. He is also a ham and has been hombrewing and studying PLL circuits since their introduction to the retail market.

You will also have to consider adding FM (relatively easy) and repeater offsets. It is a good project, and even if it doesn't perform as well as a "store bought" rig, the experience that you will get has a value that no price can be set on.

Good Luck

>
> 73,
>
> Thomas KI4N

Yeah, it's kind of funny sounding. This only applies when a PLL is being
used with a precise reference, for example in a frequency synthesizer.

What is happening is that the reference oscillator (often a TCXO or
oven controlled Xtal oscillator) typically has VERY good phase noise.
Any phase noise from the VCO (which tends to be pretty bad in this
respect) shows up as an error from the phase detector (typically a mixer).
The low pass filter can respond to this error if it falls within the
passband, but otherwise it can't and the VCO runs "open loop." So
what is happening is any phase noise out of the VCO shows up as
an error and gets corrected by the loop, provided it falls within
the loop bandwidth.

Afer you know the "why" it becomes obvious that to make this work
you've gotta have a very low phase noise reference.

Wow... Old English. Presumably that is the pre-1883 version!
Are you sure that the book isn't called "Reference Data for Industrial Archaeologists"?

> I
>would hope the part of the world that's been smart enough to go metric
>has also converted to simple metric diameters and thicknesses in place
>of gauge numbers, but I guess old habits die hard.

It varies a lot in Britain. Steel, wood and building materials have come in metric sizes for many years now, but most of them are uncannily close to the old traditional inch sizes!

Aluminium is only available with an extra "i", and comes almost exclusively in inch dimensions for rod and extruded sections, and SWG thicknesses for sheet. Tubing comes in inch outside dimensions by SWG wall thickness. Copper wire is still available in SWG sizes, but is rapidly moving over to millimetre diameters.

Nuts and bolts are a "mindfield" (as my dyslexic friend so aptly says). In the car industry we'd just become accustomed to US sizes (American Fine) when it all went metric, in a pincer movement from Continental Europe and Japan. For amateur radio construction we all used to use even-numbered BA sizes (British Association of something-or-other) and then that too went metric. Metric bolts are easy to use, because the size of the bolt is also the size of the clearance hole.

Never did understand any of this American 4-32 stuff...

In spite of this confusion, almost all professional mechanical engineering in Britian is "born metric". Children aren't even educated in feet, inches or pounds any more, so maybe in a few generations they really will need a reference book to learn about the old units!

>Thank goodness US
>manufacturers are getting metricized, even though our kitchens and
>roadways are still miles and ounces and tablespoons...

Roads are still in miles and mph, but British cooking recipes have always tended to work by weight. This is fortunate because ounces are the same the world over, but your cups, pints and gallons are different from ours. Since my wife is from the USA, our kitchen works in four different kinds of units: ounces, grams, US cups and British cups. And as well as degrees F and C for the oven, there's the Gas Mark system...

Aaargh! But it does keep you pretty nimble on the pocket calculator.

You can do this, but it can get noisy.
The power good is an output to the motherboard, not an input.
You will probably have to build some type of 'filter' board to feed the
output thru,
in order to clean it up a bit, maybe a big cap and a couple chokes.
Also, most supplies will not work unless there is a load on them.
Usually any line will
work, but you can smoke the switching transistors if there's no load on
it.

Enjoy,
Phil

Ramsey Electronics sells a varactor-tuned 2 meter FM receiver kit for
about 29.95, it can easily be converted to crystal control, and works
well as is for a usable 2 meter ham receiver with squelch etc. This is
barely above the cost of buying the parts themselves.

This is beginning to sound like the opening exchange that we heard each week on "The Prisoner" between No. 6 and No. 2. ".....who is Number 1? .....You....are Number 6....."

"Who at Varian gave you that information?" ..... "Who is Mr. XXX?"

It just goes on and on....

You've got a lot of nerve to ask Rich for a name, when you have catagorically refused to name the mysterious Mr. XXX.

And you really should stop accusing Rich of saying that the dissipation rating of an 8877 grid is 500 watts. That's not what he's said, Tom. What he said was that it might take that kind of power to elevate an 8877 grid to the point of boiling gold in the instant of time it takes to trash one of those tubes. At least, that's the way I interpreted it.

And your denial of the possibility of cathode damage in some of these scenarios is wrong, too. Some of these cathodes are indeed pretty vulnerable to certain types of damage.

Hello all,

Is there such a thing as a Direct conversion FM receiver, similar to designs available for CW and SSB reception? Sensitivity isn't a premium.
I've heard about mini FM receivers for the broadcast FM band (such as "wrist watch" or "necklace" versions), that might implement such a concept.
Any pointer in the proper direction (either theoretical or a practical design) would be truly appreceated, including if there is a difference between a WBFM and a NBFM design.

There are other approaches than using IF stages. I read a ham
article a few years ago that suggested that TRF-type receivers, in
which all the amplifying stages are tuned, might be worth trying.
This was tried in the early days of radio, but having all those knobs
to tune was a big pain. Today we could make all the stages self-tuning.

Another recent cute idea is being used in some cell sites.
They downconvert the entire cellular band to an IF frequency,
digitize the entire band, and crunch on the results with DSPs to
extract all 800+ channels simultaneously. For fully populated
cell sites, it beats having 800 FM receivers.

Many years ago (about 33!) I built a simple FM radio using an RCA tunnel diode. I believe the circuit was in one of their semiconductor data books, but I don't remember the name of it.

The tunnel diode served as a mixer and an oscillator, but there was only one tuned circuit. The if was essentiallly 150 kHz or so. There were no tuned elements in the IF stages. The IF circuit was several (4) cascadeded limiters of two transistors each. The output of the limiter stages triggered a one shot with fixed pulse width for every zero crossing. The one-shot output was averaged to provide the detected audio.

The circuit occupied a 4" X 9" perf board when made from discrete components. I still have it. It actually worked pretty well. The biggest problem was interference from AM stations overloading the front end if you made the antenna lead too long. I used it for background music in my shop for several years with just a twin lead dipole.

The neatest thing about it was that it didn't take any fancy equipment to get it going. One could probably duplicate it more compactly with modern IC's, but you'd probably want to do something different than the tunnel diode front end.

On the other hand, there are some nice chips out there that don't require too many add-on parts to make an FM radio. And, you can buy a small FM radio with earphones for $9.95 at Wal-Mart.

The radiation pattern from a typical inverted V antenna will show horizontal polarization in the broadside direction and vertical polarization off the ends. Which polarization is dominant depends upon the included angle and the height above ground. For 6 meter skip, polarization won't make much difference. On 2 meter FM, you'd probably be better off with a simple quarter-wave vertical.

You could try and check out the Philips TDA7000 series, if it still
exists. It has an IF of around 75kHz, in order to get around most
problems of image response, the theory being that if you have a
relatively strong transmitter 150kHz away, either your wanted signal or
the interferer is out-of-grid, and you will have problems anyway with an
el cheapo receiver.

Of true zero-IF receivers (with a selective PLL demodulator operating at
100MHz) I have no idea. But I guess you might run into some serious
problems.

Yes, I *do* have something with these guys. But I won't see it in my
paycheck whether you buy Philips or whatever other brand you like, so go

ahead.

Regards,

Onno

I have a couple of variable caps from AM/FM portable radios.
They are small, abt 1" square, and they have four terminals and a
ground.

Looks like this is a type of four section capacitor?

What is the best way to test/measure variable caps? I want to wire
it for an AM loop antenna tuner, about 365pf.

thanks

I have some new, surplus, ISDN terminal adapters.
They are ISDN BRI external units similar to the Motorola Bitsurfer.
Features: ISDN BRI, POTs, NI-1, sync or async to DTE via 25pin 'D' conn.

While I have been selling these for $125/each, I'd be just as happy to
swap for shortwave or ham gear. New, old, dead, or alive.
My main interests are older tube type receivers, early solid state
receivers, transmitters, and transceivers, and home brew receivers.
However, being easily amused, I'll consider anything ham or SW related.

I also have some older ISDN adapters which support only DMS100 and 5ESS
but not NI-1 whick I'd also like to swap. They are also new surplus and
I've been selling for about $40/each.

A rule of thumb is that a coaxial resonator has the same Q as an air
coil of half the diameter. To get a Q of 50 at 50 MHz. with an air
coil requires a diameter of about 1/14 of an inch. Hence, you would
need coax of 1/7 inch to get a Q of 50, i.e. 0.141 semi rigid coax.
A Q of 50 is close to what you get with an ordinary 10 cent molded
inductor. So there is no free lunch here.

You can do it by doing a quadrature conversion to baseband and using
the resulting I and Q signals to find the phase of the signal; then
find the rate of change of phase with respect to time. This is
fairly easy to do in a DSP with some clever algorithms which I believe
are pretty well known. (Hope my memory is right on all that.)

You can also convert to a very low IF, digitize it, and process it
with an algorithm which is very similar to an analog quadrature detector:
just convert to, say, 20kHz IF, digitize at 80k samples/second, and
multiply each sample by the previous sample. Normalize for amplitude
(essentially the analog of a limiter stage). Run the output thru a
lowpass filter to remove things above half the IF or so. There is a
90 degree phase shift if the sig is exactly on 20kHz = fs/4, and the
output is zero. If the sig is above or below that, there is more or
less than 90 degrees phase shift, and the output will be above or below
zero. I recall the analysis I did on this (straightforward trig functions)
says the output is exactly linear, no distortion.

There are direct conversion FSK receivers used for paging.
I don't see any way this would work for analog (voice) FM,
except, as noted by others, the digitized I and Q technique,
which is more complicated that building a conventional receiver,
and in any event, is unlikely to fit into a watch with present
technology. If anyone knows how to do this, it would be the
paging watch companies like Seiko.

>I've heard about mini FM receivers for the broadcast FM band (such as
>"wrist watch" or "necklace" versions), that might implement such a
>concept.

I have one of those wrist watch radios. The one I have is not direct
conversion, rather it uses a 70 kHz. IF. It gets away with such a
low IF frequency by ignoring the stereo MPX sidebands. This works
because those sidebands have such a low modulation index that they
can be considered to be phase modulation. Of course, the recovered
audio is mono.

4068. Wanted: Tips for constructing water cooled load

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-18 00:00:00 UTC
From: jpotter@jpaw.com
Message-ID: <32b83ced.168157808@news.santafe.edu>
Source record: 99564
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

I am wanting to build a non-inductive 8 kW load for 300 kHz, CW. The application is power inverter testing, not commercial resale. My current thinking is to use Carborundum resistors with water cooling. I believe I can get away with 10 X rating with water cooling.

I am planning on using three 1" X 18", 680 ohm resistors in parallel to get 227 ohms. (Unfortunately I'm not dealing with a 50 ohm system and I prefer not to have to mess with a matching network since I may want to use this at any frequency from 200 kHz to 400 kHz.) One end of the load is grounded. The other will see a not quite sinusoidal waveform of about 2 kV peak. The water would be flowing tap water.

The questions are:

Can I really get 10 X rating?
Do I need water on both inside and out?
Are there any problems with connections immersed in water?
What is a good way to connect the water to the resistors?

Any construction tips would be appreciated.

Thanks.

Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

Just wondering if anyone has a good idea on how to mod a Realistic WX alert radio model 12-140. It seems to use one crystal as a reference for the 3 WX service frequencies. I would like to know if I could drop a crystal in there to reference something in the 147.00MHz range so I could tune it to rx 147.060 and others in the area. I am also curious what the tones are that actually set off the alarm. I would like to set it to go off if someone does a long-tone zero on our repeater. If I knew what the tones were that set it off, I could program our repeater controler to emit those tones after a LTZ.

Anyone ever try this? Does this make sense. Please reply via email and posting if at all possible.

Thanks,
JWP

The diversion was necessitated by the discovery that one of debaters was being somewht less than truthful. IMO, prevarication has no place in a scientific debate. Do you have a diffent opinion, Rick?

Did you see my reply of 16 December? I raised some technical issue is this reply to your post. Have you lost interest in such things?

In case you missed it, here is an instant replay:
Are some amplifier manufacturers incompetent? Consider the cut-and-dry issue of filament voltage. The rated filament voltage for a 3-500Z is 4.75v to 5.25v. Eimac says that the emissive life of a thoriated tungsten filament/cathode varies as E1/E2.^23.4. If you bought a commercial 3-500Z amplifier, Rick, and you subsequently discovered that the filament voltage at pins one and five on the tube sockets was 5.95v with an electric-mains voltage of 240v, would you conclude that the amplifier was competently-engineered? (such fil-v reduces life to under 1 percent of normal) // This is not a figment of anyone's imagination, Rick. The amplifier's manufacturer is Henry Radio Co. Other manufacturers have the same problem. Do you think its okay to run 15V on a 3CX800A7 filament?

Rick: Do you think 48A of filament inrush current is ok for a 3-500Z?

4079. Re: How can I dye plastic enclosures?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-18 00:00:00 UTC
From: jim@rst-engr.com
Message-ID: <597goa$q05@li.oro.net>
Source record: 99636

jdillon@acsworld.net (John C. Dillon) shared these priceless pearls of wisdom:

->I found some inexpensive plastic enclosures for my electronic
->widgets. Price, fit and form is perfect. Color is anything but.
->These are bright yellow, and I need to dye them olive drab or
->even black.

We dye nylon and HDPE all the time. The thing you need to do is get the temperature of the soak bath up to 150-190F for an hour or so to get the color into the material. Different materials melt at different temperatures, so use the highest temperature you can consistent with dimensional stability of the material you are dying.

With certain light colors into clear plastic, we have also found that the addition of a small amount (~5%) of vinegar seems to make the color less blotchy. Besides, it makes the place smell like you are canning pickles!!

I hate to sound like a complete moron, but isn't an inverted V antenna horizontally polarized? I'm thinking of getting Ten Tec's 2m to 6m transverter but don't have any room to put up an antenna. I already have an inverted V in the attic. My only 2m rig is my HT. (FM of course) Horizontal polarization won't do me much good on FM. Is that right? Is an inverted V horizontally polarized? Thanks for any help.

I've gone through considerable trouble to rid the lab of broken
75 Ohm sockets, and I never cease to harass newbies here to take
good care of connectors.

In my opinion, the people who designed the 75 and 50 Ohm BNCs to
be so closely alike that only specialists can tell them apart
deserve to be fried to a crisp.

And they did it again with N-connectors, and C, and probably some
others I haven't encountered yet.

Is it laziness, unwillingness to design a *different* interface?
Is it a conspiracy? Will they ever learn?

Ian White, G3SEK (G3SEK@ifwtech.demon.co.uk) wrote:
(in reply to something Wes Stewart wrote)

: None of my British handbooks mentions NBS, and neither did US sources
: such as the 1950 ARRL Handbook or the 1959/60 and 1977/78 editions of
: the Handbook of Chemistry and Physics.

: I finally found it in the 1941 edition of Machinery's Handbook:

: "This Standard Wire Gage (also known as the Imperial Wire Gage and the
: English Legal Standard) is used in England for all wires. The
: abbreviation S.W.G. is sometimes used for Standard Wire Gage, also the
: abbreviation N.B.S. for New British Standard Wire Gage. This gage was
: legalized in Great Britain in 1883."

: It seems that Reference Data for Radio Engineers uses wire tables that
: date back to the days when NBS really was "New"!

The newer 7th edition, dated 1986, and now called "Reference Data for Engineers," has a table, "Courtesy Whitehead Metal Products Co., Inc.," which is a comparison of various gauge standards. It lists "AWG B&S," "Birmingham or Stubs BWG," "Wash. & Moen W&M," "British Standard NBS SWG," "London or Old English," "United States Standard US," and "American Standard Preferred Thickness." (The last one isn't really a gauge number standard...) I'm sure there are others. I would hope the part of the world that's been smart enough to go metric has also converted to simple metric diameters and thicknesses in place of gauge numbers, but I guess old habits die hard. Thank goodness US manufacturers are getting metricized, even though our kitchens and roadways are still miles and ounces and tablespoons...

Untruthfulness is probably the surest way to loose public support---and
the fastest way to ruin one's chances of winning a public debate.

It's unfortunate that Mr. Rauch bailed out, Phil. This morning I got
an e-mail from Rick KC0HH, who has had two bandswitches mysteriously
burn up in his Ameritron AL-80A amplifier. Rick said: " I am really
tired of spending all day Sunday re-installing a band switch...."

In article <32B6CC17.2BE0@mail.teclink.net>, "Tom C. Brown, Jr." <madison@mail.teclink.net> writes:

>You've got a lot of nerve to ask Rich for a name, when you have
>catagorically refused to name the mysterious Mr. XXX.

Let me see if I undersatnd what you are saying. Correct me if I'm wrong.

It's ok for you and Measures to demand answers, and OK for Measures to claim some "unnamed engineer" told Foote something that Foote told Measures over the phone, but it isn't OK for me to do anything like that. It's OK for Measures to make something up about Marvin Born, and about Eimac's personnel department, and I can't challange him on it.

In the context of 500 watt 8877 grids, photons, Q reduction at VHF, arcing of low impedance circuit components, and discussions of Richard Nixon and flaming Pintos I guess that makes sense.

>And you really should stop accusing Rich of saying that the dissipation
>rating of an 8877 grid is 500 watts. That's not what he's said, Tom.
>What he said was that it might take that kind of power to elevate an
>8877 grid to the point of boiling gold in the instant of time it takes
>to trash one of those tubes. At least, that's the way I interpreted it.

Richard **VERY plainly** said HF excitation can not damage the grid of an 8877 because it takes 500-700 watts to damage the grid. That claim was at the root of the idiotic suggestion to remove electronic overload and add resistors for "fuses".

Richard claims a 100 watt exciter can not damage a 4 watt 3CX800 grid, or a 20 watt 8877 grid. That's a harmful and misleading claim.

>And your denial of the possibility of cathode damage in some of these
>scenarios is wrong, too. Some of these cathodes are indeed pretty
>vulnerable to certain types of damage.

1.) Measures claims a pair of thoriated tungsten cathodes in 3-500s saturate at 150 watts. This allows him to "prove" the tank can't be overdriven by exciter overshoot.

2.) Measures claims a parasitic or a PHOTON can cause several dozen or hundreds of amperes of current in the same tube. This allows him to "prove" a parasitic causes tube failure.

Which is it, number one or two? Can't be both.

1.) He claims the tank tuning capacitor is a high impedance at VHF so the capacitor and bandswitch can arc.

2.) He claims the addition of nichrome lowers the Q, which means the impedance of the tank tuning capacitor must be very low. The impedance must be close to or less than the impedance of the nichrome wire or the Q won't change much.

Which is it? It can't be both.

He plainly contradicts himself and physics at every turn.

About the cathode damage?

A 3-500Z has a saturated current of just over ten amperes.

While both MOX and tungsten cathodes can saturate, only MOX cathodes are prone to unrecoverable loss of emission from excess cathode current. A thoriated tunsten cathode can stand repeated saturation over and over again with no damage.

The last thing you want to do is reach emission limits in a MOX cathode tube. People read articles (by RLM) suggesting heater voltage be reduced to the minimum required, and they RUIN 8877 and 3CX800 tubes !!! Reducing heater voltage increases the likelyhood of damage nearly as much as excessive voltage does.

You will not strip the cathode of a MOX tube with even twice the rated operating cathode current if the heater voltage is high enough, but if the heater is set too low the cathode can be ruined in normal rated current operation.

This is too complex to discuss here, but the bottom line is it's ok to run a thoriated tungsten filament tube at reduced filament voltage, but not the heater in a MOX cathode tube.

I haven't opened up this version of the radio, but I converted several of the weather cubes that RS used to sell. All that was required on them was changing the resistance of the reostat on the tuning circuit, I don't remember the exact values, but they used a variactor which had enough range to get down to the 2 meter band.

Okay, Rick, back to technical matters.

About 14 hours ago I received a telephone call from Jim, KA3JSO. He wanted to talk about designing suppressors for large amplifier tubes. We talked for over an hour. During the course of the discussion, he told me he once owned an AL-1500 amplifier. As you may recall from a previous post on this thread, the AL-1500 uses no VHF parasitic oscillation suppressor device. Jim told me that during the 12 month warranty period, two 8877s failed suddenly. After 8877 number three was installed, Jim sold the amplifier as soon as possible. Jim said that Ameritron told him that the failures were caused by defective 8877s. Jim told me that K20JL/V31BB had an AL-1500, in which a number of 8877s suddenly failed About 8 days ago, Marvin Born, KF8XU, telephoned me. He said he needed a parasitic suppressor retrofit kit for an AL-1500 because the one he was attempting to repair was producing intermittent VHF oscillations, as seen a a Tek 454 scope. Marvin said he could also see the intermittent VHF oscillations on a spectrum analyzer.

With the exception of Ameritron, all manufacturers of 8877 amplifiers seem to use a VHF parasitic oscillation suppressor device. IMO, there must be a reason.

Rick: Do you feel that the relatively large number of 8877 failures in AL-1500s is due to an 8877 manufacturing defect at Eimac?

There are lots of reasons why oil is the preferred coolant for such
applications. Here are a few:

1. Corrosive characteristics of hot H20
2. Conductive " " "
3. Energy storage " " steam
4. Very high dielectric constant of H20

There was a pretty good write up on one of these in either 73 magazine
or RF design within the last couple of months (I'll try to find the
article and post the reference to it) - It included both the theory and
the measurements. It was basically what they called a "stabilized VCO".
As I remember it, the VCO was built with high Q components so as to
minimize the basic phase noise of the oscillillator, and then a very low
bandwidth correction was used (time constant of several SECONDS) to keep
the oscillator from drifting more than 1-2 Hz from the wanted frequency.
The article professed that the major improvement in close-in phase noise
was primairly due to the high Q of the oscillator tank. The set up was a
bit slow to tune, but the phase noise was apparently quite good! (I know
that this is still a simplification... the article was about 4-5 pages
long! :o)

I used a Motorola MC 100 E 016 FM. It works until 750 MHz or so.
It's even presettable, but gets really hot.

Superregenerative receivers will detect FM signals. It's been a while since I've read up on them, and I can't remember whether they do the detection due to slope detection (where an AM receiver is used to demodulate an FM signal by mistuning it, so the frequency variation becomes an amplitude variation since it's sweeping back and forth along the skirt of the receiver's selective circuits), or if FM detection is some inherent part of superregenerative detectors.

Superregenerative detectors are among other things, very wide band. They'd probably work for FM BCB signals, indeed I think probably some simpler receivers from days gone by did that, but to use one to detect narrowband FM, such as 2m signals, will result in little or no recovered audio.

You can't get much simpler than a superregen receiver. One transistor detector, followed by an audio amp.

A phase locked loop would qualify as a "direct conversion" fm receiver. But running a PLL at VHF, where I presume you want to detect a signal, might be problematic. First, finding a PLL that runs okay at that frequency. Then, again the recovered audio is a product of how large the deviation is. In a superhet receiver, the signal is moved to a lower frequency where the deviationis a larger percentage of the if signal. Running the PLL at the signal frequency, deviation is a much smaller percentage of the signal frequency. Again, it would work better for the wide band deviation of FM BCB signals.

While you have that receiver open, can you give us any details of what's inside? Years ago, I had a Radio Shack weather receiver, and it amounted to a FM BCB receiver, moved to the weather channel. It was varactor tuned, and went to a 10.7MHz if. The filtering there was only IF transformers, no ceramic filters.

I had assumed that the weather receivers of today were a fancier design. But I bought some scrap hand held CB sets recently for parts, and their built in weather receivers had a single conversion design, and the crystal does not translate to any standard IF frequency. I need to do some more calculating to figure out what's going on.

Is there a second conversion in that weather receiver? You should be able to uncover that information by looking for a second crystal elsewhere on the circuit board.

Are there any ceramic filters? If the circuit fits the usual pattern, there'd be one at 10.7MHz (maybe marked with that number), which might look like a ceramic capacitor except it has three leads. Then maybe there'd be another filter, in a square plastic package maybe, most likely running at 455KHz. I have no idea whether this presumption is valid, but if it's a good quality receiver, then it probably would be double conversion 10.7MHz/455KHz and most likely at this date uses an IC for the IF strip, if not for the whole receiver.

This information would be useful to others. If the circuit is double conversion and uses ceramic filters, then they are well worth converting to 2M use, and would provide a cheap means of getting a 2M monitoring receiver, which many seem to desire.

If it's a much simpler circuit, it still might be useful in some cases, but less so and not something that I'd spend much money on.

Brian,
This might not be a programming way of doing it but
you can use the sound blaster to RECORD the touch tones from your phone
and
save that touchtones to several files

You could then
at dos level
type in
play 1.wav
play 4.wav
or
1.voc
or howevery you recorded in in whatever format you recorded it in

I do believe that there was a program that will generate the touchtones
but I cant remember the name of it

Good luck

4101. Re: Good source for amplifier tips

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-19 00:00:00 UTC
From: tomb@lsid.hp.com
Message-ID: <59c4i0$nut@hpcvsnz.cv.hp.com>
Source record: 99461

R. L. Measures (measures@mail.vcnet.com) wrote the following piece
of ambiguity::

: Are some amplifier manufacturers incompetent? Consider the cut-and-dry
: issue of filament voltage. The rated filament voltage for a 3-500Z is
: 4.75v to 5.25v. Eimac says that the emissive life of a thoriated tungsten
: filament/cathode varies as E1/E2.^23.4. If you bought a commercial 3-500Z
: amplifier, Rick, and you subsequently discovered that the filament
: voltage at pins one and five on the tube sockets was 5.95v with an
: electric-mains voltage of 240v, would you conclude that the amplifier was
: competently-engineered?

This leaves me with the following questions:

-- Did you indeed measure 5.95 volts, or is that just part of a
hypothetical question?
-- Is that 5.95 volts a true RMS voltage or is it a voltage you read on a
peak-sensing rms-calibrated meter?
-- Is the meter accurately calibrated, and was it read accurately?
-- Was the primary side wired for 200V, 220V or 240V when the measurement
was made?
-- Is the meter accurately calibrated, and was it read accurately? (240V
side)
-- Was the measurement made with a tube in the socket which provided the
expected filament load current?
(-- Which Eimac was it that said that?)

Those may not be all the things that need to be better nailed down in
looking for an accurate answer to the questions posed.

Clearly some subset of all amplifier manufacturers are incompetent by
some measure. (oops, sorry. ;-) But then I suspect a much higher
percentage of posts to this group contain inaccuracies than the
percentage of commercial amplifier manufactureres which are incompetent.

4102. 2m FM project for Theater

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-19 00:00:00 UTC
From: btbmag@ro.com
Message-ID: <btbmag-1912961503330001@news.ro.com>
Source record: 99462

Being new to ham radio, and having a problem that could be solved with ham radio, I thought I'd ask some help for a litte project.

For a play I am directing, I need to turn on a switch remotely. (BTW, the play is being performed by my Youth Drama Team at my church.) I thought that it might be possible, and simple, to create a reciever that would throw a relay after receiving a code from the tone pad on my handheld.

What I was thinking was a simple little reciever that received on a set frequency. I could then dail in that frequency on my handheld and send the correct tones to the reciever.

Recently I saw a similar plan that used the subaudible tones to turn on two devices. In the example I saw, it was used to turn on a speaker. While I like the idea, and perhaps I should use the subaudible tones as a "safty," I don't want this to be tripped by any FM signal that has those tones. I want to be able to "type in" a tone to activate the switch.

Once I get this figured out, I thought that perhaps that more switch could be added using different "codes."

Anyway, this may be to complicated for my first project. I've got a fairly long timeline, about two months, so any help would be appreciated.

Please feel free to email me or respond here.

Thanks,
Michael Malone

I have a circa 1936 homebrew (by W1ABY, SK) Class B push pull amp in need of resurrection. Amp was good for 1500W plus plus many years ago. Resides in a 5 foot high open frame cabinet. Has all original tubes but most need to be replaced. Weighs perhaps 75#.

No shipping obviously. If you live in New England and are looking for a challenging boat anchor project, let me know. Price is very cheap (to be negotiated).

Seems like transformer oil would be better and immerse the resistor assemble totally. You didn't say if this needed to be a continuous duty power rating. The old Heathkit Cantenna dummy load did this trick.

If you use water that will get to the connections, I think you will need distilled water so it will not conduct the electrical current, much like the high power broadcast transmitters with water cooled finals and plastic hoses.

Take a look at the photos in "Parasitics Revisited", in 9/90 and 10/90 QST magazine, folks. The cathode coating was stripped by overdrive, creating a dead short from the grid to the cathode. However, the gold plating on the grid is undisturbed, and no gold melt-balls were seen through a microscope. Does HF overdrive cause the gold plating to sputter/evaporate? Tom Rauch says absolutely yes, but the photographs say no. What does Eimac say? Eimac told me, both on the phone and in a letter, that gold evaporation is caused by an "oscillation condition". // Take a guess whether or not Tom Rauch took me up on my offer to dissect and photograph, for everyone here to see, a 3CX800A7 which Tom says was ruined by overdrive? If you guessed that he did not take me on, congratulations. Apparently, Tom does not have the courage of his convictions. // Next Question: Rich: Do you enjoy arguing with schmucks?

> A 3-500Z has a saturated current of just over ten amperes.
>
Not according to Eimac. Saturation begins around 1.3 amperes. Does Tom Rauch know better than Eimac? Wait a minute. We've been here before. Am I talking to a brick wall?

I think part of Mr. Rauch's problem is rooted in his reluctance to admit mistakes. Here's an example from an e-mail he sent me:
===============
Hi Rich,

I don't want to keep trashing you technically in front of people. Please consider what you say before you post it. People will think you are an idiot if you keep this stuff up.

Isn't there a way we can just end all this crap? I'd gladly agree your nichrome isn't harmful, and even may be a good solution in some special cases, if you'll just drop all the other idiotic suggestions.

Coming after me will get you nowhere, I've done this stuff for 25 years and don't often make mistakes. You might catch me once or twice out of a few dozen tries, but mostly these arguments will make you look dumb. Neither one of us likes that.

Think about it please,
Tom

==========
Some differences between Tom and me:
I have doing this for 41 years, I have made plenty of mistakes, and I know

It's apparently not a fluke. More than one model is involved. No way to adjust the filament voltage is incorporated.

A while back, I got a phone call from a fellow who owns a Commander 3CX800A7 amplifier. He told me that he had just measured 15 volts at the heater pins on the tube sockets. He asked me what I thought about it. I told him that 15v was greater than Eimac's maximum rated filament voltage. He phoned the manufacturer of the amplifier and discussed the matter as you recommended, Rick. He was told that 15 volts is perfectly okay.

However, when 15 volts is applied to the 3CX800A7 heater, barium boils off the cathode and redeposits on the grid, greatly shortening tube life.

It was not a hypothetical question. The first time I worked on one of
these amplifiers, I noticed that 3-500Z filament was so bright I could
read a newspaper with the light from it. This was no fluke, Tom. At the
time, the line voltage measured 240v with my John Fluke DMM.

You are only guessing until YOU make the measurements, Tom. I made the
measurements. I wrote about them in "The Nearly Perfect Amplifier" in the
January 1994 issue of QST magazine.

Have you noticed that QST NEVER measures filament voltage, and NEVER
measures filament inrush current in amplifier product reviews.

1:1 maybe, but not much RF out the other end. Better to use much less
cable and properly match at the antenna.

Hi All... I have an old Johnson Viking 352D 23 channel CB that I would like to get going on ten metres. I know that they can be converted to 28 Mhz and that a switch to provide a 5kHz offset can be provided.

Does anyone know how to do this? I have a similar set I bought that was already modified, and it's a real good radio - the receiver is better than my Kenwood TS120V.

The "snout" (center pin/insulator/ground fingers) protrude beyond the bayonet ring more (about .06 to .1 inch as I remember) on the plug. It will not readily mate w/ standard BNC. There is also a SHV connector which is rated for even higher voltages - the insulator/gnd fingers extend further yet and center contact is recessed... _Woody_

I have a Collins Spectrum 2000 H.F. amp, Model PA-2000 (yes, the Dessert Storm surplus is hitting the market!). It uses 8 SRF-3513B devices in the final. This is a proprietary number made my Motorola for Rockwell. I need data on the devices in order to construct a power supply for the amp. Surely there is a generic "MRF" equivalent number for these devices. Any leads or tips will be appreciated and acted upon.

Thanks!
Phil, K5PC philk5pc@connect.net

Thanks to all that replied...I am running an old IBM PC and not windows, so unfortunatly I cannot use any newer windows packet programs...I found the problem that was preventing my system to work..Two actually.,..1 The TNC required a reset by removing the lithium battery. Something was not compatable with my computer..2 There was a flaky connection in the TNC to Radio cable...After finding and correcting these two items the thing went right to work...Now, however, I am still looking for suggestions for a more efficient terminal program...Bitcom does not allow me to save incoming stuff to disc or to scroll back thru stuff that has gone by on the screen..Any suggestions? Remember, this is an old system...640K memory & 360K drive. I do have a 30Meg hard drive in it...The reason I am using such an old computer is because it was free...Thanks.

: >higher Q. Worked pretty well in an oscillator that tuned from 40-50 MHz.

: A rule of thumb is that a coaxial resonator has the same Q as an air
: coil of half the diameter. To get a Q of 50 at 50 MHz. with an air
: coil requires a diameter of about 1/14 of an inch. Hence, you would
: need coax of 1/7 inch to get a Q of 50, i.e. 0.141 semi rigid coax.
: A Q of 50 is close to what you get with an ordinary 10 cent molded
: inductor. So there is no free lunch here.

I don't think that rule of thumb applies in this case - The 1/4
wavelength inverts the reactance of the C so that it looks like
an L. I wasn't making an inductor by winding the coax into a circle.

: I am wanting to build a non-inductive 8 kW load for 300 kHz, CW. The
: application is power inverter testing, not commercial resale. My
: current thinking is to use Carborundum resistors with water cooling. I
: believe I can get away with 10 X rating with water cooling.

You can use a dielectric fluid to cool the system, basically, you would run this fluid through the resistors and possibly on the outside as well (it's obviously non-conductive) and then the heat generated will evaporate the fluid which is then run through a heat exchanger and a pump which generates enough pressure to spray the fluid on the resistors.

FYI: the fluid is a derivative of freon but with a much lower boiling point so the compresser and evaporator is unneccesary. In either case, because the fluid is converted to a gas its heat transfer capabilities are exceptional.

Most PC Power Supplies require a load on the 5volt or they shut down due to over-voltage on the 5 volt line. I have seen them work fine this way with just a
1/4 amp load. For the non-electronic folks, that a 20 ohm resistor, 2 watt minimum.

The +12v and -12v lines don't require a load.

Water is not as good a conductor as you might imagine. Some of the
most compact 50 ohm rf dummy loads have ordinary tap water directly on
the load resistor. I don't know the details of how it is constructed,
but I own a 5 kW 50 ohm load mad that way. The load I need for this
project is about 250 ohms.

Someone suggested a transformer to match a 50 ohm load. I'm looking at
that possibility. It won't be cheap, but it looks cost competitive
with both a custom resistive load and a matching network, even
considering that I have to buy another 5 kW 50 ohm load.

Thanks for your input.

> code from the tone pad on my handheld...

Sure. Look in back issues of 73 for the Intelligent Relay, a little doodad that plugs into a receiver, listens to DTMF tones and controls things for you. It uses a DTMF decoder and a Parallax Basic Stamp, so you can program more-or-less any access code you want for multiple functions. I don't have the issue details handy, but poking around Parallax's web site (www.parallaxinc.com) might provide a pointer.

> What I was thinking was a simple little receiver that received
> on a set frequency. I could then dial in that frequency on

Yes. For what you want, maybe one of Ramsey's VHF FM receiver kits would get the job done? Or creatively retune an FM broadcast receiver? Cheapie portables are cheap enough to blow up if you goof.

> (snip...)
> Once I get this figured out, I thought that perhaps that
> more switch could be added using different "codes."

This is where the Intelligent Relay shines, because you can add more codes and functions by reprogramming it.

> Anyway, this may be too complicated for my first project.
> I've got a fairly long timeline, about two months, so any
> help would be appreciated.

Too complicated? No. Take it a step at a time. Obtain, build (or modify) and test the receiver. FTP the Basic Stamp documentation and programs and order a Stamp - either a pukka one from Parallax, or one of the many clones. Program it. Control things with it.

Above all, have fun...

>

I have to say that none of the above makes sense at all to me.

First, there is no difference between a tube in an "oscillation condition" and a non-oscillating amplifier, so far as the tube itself and its ratings are concerned. The external difference is the source of the drive (or over-drive) - either from an external source or from feedback - but the same level of drive is going to look the same to the tube no matter where that drive came from. Look in old transmitting tube manuals and you will find operating conditions specified for "RF Power Amplifier and Oscillator." Archaic technology, but still valid.

Then there is the question of whether VHF overdrive is signficantly more damaging to the tube than HF (or audio, or DC) overdrive. In a tube that is specified for use at full ratings into the lower UHF range, as is the 3CX800A7 being discussed here, this seems unlikely.

When you say "The cathode coating was stripped by overdrive" do you mean that the grid current was excessive or that the cathode current was excessive?

You have two specimens of trashed tubes, with different failure mechanisms. I don't see how you are able to associate the failures with HF vs. VHF damage - it seems much more plausible that the grid was damaged by excess grid dissipation (independently of frequency), and that the cathode was damaged by excess cathode current, perhaps combined with low filament voltage.

Thanks for the suggestion. I once made a waveguide load for a few kW
at 425 MHz with a tilted waveguide partially filled with water. It
worked great. I hadn't thought of it here because one of the waveguide
load was that it was tapered over may wavelengths and didn't require
complicated adjustments to get a good match.

I also remember that the father of a friend of mine told me about make
dimmers for 1 kW lights in the 30's by dipping 2 electrodes into a
container of salt water. And, of course, most of us are familiar with
the water "vaporizers" that are just two electrodes in a container of
slightly salt water. So, it might work.

My test-bench 12 volt supply is three 5-volt 120-amp switching power supplies wired in series. I've turned each one of them down to 4.5 volts giving me a very nice clean 13.5 volt supply. The ones I have seem to regulate properly even with no load.
- Brian

The difference is that at HF there is a load. At VHF there is virtually
no load. In a high mu triode, when there is no load, the grid current is
going to be astronomical.

>The external difference is the source of
> the drive (or over-drive) - either from an external source or from

Very good, Andy. Modern tubes still use the same terminology. Modern
tubes can oscillate.

> Then there is the question of whether VHF overdrive is signficantly more

> excessive?

Excess grid current does not cause the cathode's strontium oxide and
barium oxide emissive-coating to separate from the cathode. Cathodes are

principally damaged by excessive cathode current density in the
emissive-coating, or by operating the heater voltage outside the
recommended range, or by an insufficient preheat period.

> that the cathode was damaged by excess cathode current, perhaps combined
> with low filament voltage.
>
The amplifier that produced the tubes with the damaged cathodes and
undamaged grids was a Henry Radio 2K Ultra, which uses two 8873s. The
filament voltage was reportedly normal (K5JV). The drive power was
reportedly around 200wpep, as supplied by a Drake T4 (K5JV). The rated
drive power for an pair of 8873s is about 55wpep. The owner of the
amplifier had been warned that 200wpep of drive might damage the tubes.
Eventually, the tubes shorted from flakes of cathode coating that lodged
between the grid and filament. However, the grids appeared to be in
perfect condition. No gold melt-balls were seen. The point is this: If
a tube is overdriven by HF energy, the first thing to go is the cathode
coating.

The amplifier that produced the tubes with gold sputter damaged grids was
an Alpha. Two of the 8874s were severly gold sputtered, and one of the
8874s was apparently undamaged. The cathodes of the two gold sputter
damaged 8874s were largly intact. To me, this suggests that that the
tubes were not being overdriven when the failure occured. Eimac says that
gold sputtering is caused by an oscillation condition. I believe it. //
Since all three tubes were connected in parallel, equal HF drive was
applied to the three tubes. How is it that two tubes were suddenly
destroyed and one tube was undamaged? IMO, an anomaly is indicated.

It may be possible to cause gold sputtering by HF overdrive, however, if
the first thing that occurs during HF overdrive is a dead short between
the cathode and the grid, how is it possible to continue driving the tubes
into other failure modes, Andy? .

>
Not at all, Mr. Rauch. You can challenge me on anything you like. BTW, I never demand answers, I only request them. How many times did I ask you whether or not your AL-1500 8877 amplifier design uses a VHF parasitic oscillation suppressor. You never did answer. Are you hoping that nobody noticed? What were you trying to hide, Mr. Rauch?

So you expect people to believe I made it all up.
MARVIN C. BORN's callsign is KF8XU. He lives at 7956 GREENSIDE LN WORTHINGTON OH 43235. He is in the process of repairing/modifying an AL-1500 that he says currently has an intermittent parasitic oscillation. Anyone who thinks I made it up should contact Mr. Born directly. He has an assortment of test equipment and he appears to know what he is doing. We shipped vhf suppressor retrofit kit s/n 4548 to him about a week ago.
// Jim, KA3JSO is yet another amateur radio opeator who apparently had parasitic oscillation problems in an AL-1500. When he was on his third 8877, he decided to sell the troublesome amplifier ASAP. Jim told me that K2OJL/V31BB also had multiple 8877 failures in his AL-1500.

Mr. Brown recently noted that Mr. Rauch seems to have the uncanny ability to promote and demote Eimac personnel. For example, Willis B. Foote was demoted from Eimac's Chief Specifications Engineer, Power Grid Division to a lowly letter writer by the formidable Mr. Rauch. What is even more amazing is that Mr.Rauch was somehow able to demote Mr. Foote some ten years after he retired from Eimac. Mr. Myklos is another example. According to the personnel department at Eimac's Salt Lake City plant , Mr. Myklos was an "Engineer B" during his employment. However, thanks to Mr. Rauch, Mr. Myklos was retroactively promoted to "R+D engineering manager". The power of our "recognized amplifier experts" is totally

awesome.

After the good luck I had talking to the personnel department at Eimac's Salt Lake City plant , I decided to try San Carlos to see what I could find out about the mysterious Mr. Reid Brandon.

Mr. Brandon works in marketing. I wonden why Mr. Rauch was trying to keep this a secret?

Hi Rich--

In your post, you wrote: "Rick, and you subsequently discovered that the filament
: voltage at pins one and five on the tube sockets was 5.95v with an
: electric-mains voltage of 240v, would you conclude that the amplifier was
: competently-engineered?"

I might do many things--including discussing the matter with the manufacturer's customer service engineer before making assumptions about the amplifier's "airworthiness" or condeming the designer's petigree. A problem such as this, if indeed the incident occurred exactly as you represent, could just as easily be the consequence of a transformer manufacturing problem--or a failure on the part of the owner to read the manual. And, even if the problem was "real", it may be due to manufacturing substitutions or production changes the designing engineer knew nothing about. Your anecdote is provocative (as I'm sure you intend), but I have no confidence that it is complete. Like Paul Harvey, I don't think I could even comment without hearing "the rest of the story".

4139. WTB: Old SB-xxx chassis for homebrew project

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-20 00:00:00 UTC
From: gekko95@ix.netcom.com
Message-ID: <59d07e$1br@sjx-ixn6.ix.netcom.com>
Source record: 99476
Cross-posted to: rec.radio.swap,rec.radio.amateur.homebrew,rec.radio.amateur.equipment,rec.radio.amateur.boatanchors

Hi! I just bought an old SB-102 chassis with all of the parts removed for $15 to use as a homebrew project chassis. I plan to repaint, and cover the faceplace with a new thin sheet of aluminum for my new rig to live in. (2 stage, 30 watt all band CW rig with built-in VFO)

Well, I need another and possibly 2 more - one for a matching receiver I'm planning, and another for a small amplifier.

So I am looking for ANY SB-xxx chassis, completely stripped of parts or not - don't care what the model was - even could maybe use smaller boxes, like old SB-610 scopes or speaker boxes, or whatever. Again, I am after the boxes and the innards are not important (although if any parts still remain, they would be put away for future homebrew)

Cheap is kind of important, though. That's why I am specifying no parts and looks are unimportant, as long as no dents or cutouts that would be tough to paint over. $10 to $20 is the range I was thinking.

email to Dave gekko95@ix.netcom.com

Thanks to anyone who replies!

(PS - I now have 2, and the transmitter is coming along. Gathering parts for the receiver. Now if I can find another SB-xxx box for the 811 amp, and maybe a speaker box, or other similar SB-xxx.... 73's

>big transistor to the 5v size (to ground) to let it see a little
>load?

All of the PC supplies I've seen require a load on the 5 volt bus to operate correctly. Usually a couple of amps draw is enough to allow them to maintain regulation. A pair of 10 watt 4.7 ohm power resistors in parallel forms a good load. They're switchers, of course, and need a load to operate correctly. Usually the regulation is done on the 5 volt bus, and the other voltages just follow this.

Most PC supplies only have about 2 amps capacity on the +12 volt bus, and that isn't enough to power much of an amateur radio. The bulk of the current capacity is on the 5 volt bus, which may be able to source 20 amps. Newer supplies also often have a 2 amp capacity on the -12 volt bus, but older supplies could only source a few hundred milliamps on the -12 volt bus.

Mostly, I consider PC supplies merely as a source of parts for amateur radio work. They aren't of much use as power supplies except in computers and other things which need lots of 5 volt current. They also often generate a lot of RF noise, and RF ingress can cause them to lose regulation and allow the output voltage to soar to very high values. That's a recipe for fried radio.

Hi Tom,

I agree with all your points.

I'd like to add an area I consider of major concern to the list. In spite of all the free-flowing "carte blanche" criticism of everybody else in the world, technical descriptions of how to measure things are almost totally missing. The "helpful" suggestions are based on the author's view "everyone else is incompetent and a liar".

Important data is often left out of the "suggested improvements".

Over the past year I have seen three PA's with metal oxide cathode tubes (two 8877's, one pair of 3CX800A7) ruined because someone reduced filament voltage to "improve" tube life. Unlike the "intermittent parasitics" claim, this problem is repeatable and directly traceable to a modification.

Briefly, while reducing cathode temperature does improve emission life it pushes the tube closer to emission saturation. This has two deleterious efffects.

1.) In metal oxide cathode tubes it increases the required warm up time as well as lowers the peak emission capability. If the user pushes the tube current (on peaks, not on the current the panel meter indicates) to this limit, the cathode suffers slow irreversible deterioration. This causes

unrecoverable loss of emission.

2.) In a thoriated tunsten tube reduced filament voltage does not decrease tube life (the tube is not harmed when the catode is operated at its' peak emission capability). Warm up time is also inconsequential. But reduced filament voltage does decrease linearity and increase IMD products long before a reduction in power is noted.

It's best to run all amateur service tubes within the range specified, unless the user knows exactly what to do and how to measure it. If it were my PA, and Eimac gave an operating range of 4.8 to 5.2 volts, I'd be sure the voltage never went outside that range. I'd measure voltage at the pins with a good true-RMS averaging meter.

If I had a tube running at 1/4 its rating, as BC stations do, I would reduce voltage below the recommended values (while being very careful to not go too close to the edge of emission). If I was using the tube at its published rating, I'd run it at the rated voltage.

73 Tom

4146. Plans for 70cm duplexer?

You might want to check out Coolwave. Syntrillium has a web page where
you can get Coolwave. Coolwave will allow you to generate single tones,
DTMF or those odd CCIT DTMF like tones. While Coolwave is "crippled" as
shareware (you can register it for $50), you are allowed to use any 2
of its' many functions as shareware. I think there are versions for both
Windows 3.1 and Windows 95.
Good luck.

tomb@lsid.hp.com (Tom Bruhns) shared these priceless pearls of wisdom:

Tom -- help me here (I'm an analog cat in a room full of digital rocking
chairs)

->You can also convert to a very low IF,

Understand. Mix it with an LO that is close to the desired. One small
problem is desense of the RF stage with the LO, but that is an RF problem
and not a digital one. That I can handle.

-> digitize it

in what sense digitize? Sample at some higher frequency than the IF and
recreate the IF frequency as a bunch of analog dots? I honestly don't
understand what it means to digitize an analog signal other than sampling
and recreating the same analog signal as a whole potful of digital levels.

, and process it
->with an algorithm which is very similar to an analog quadrature detector:
->just convert to, say, 20kHz IF, digitize at 80k samples/second, and
->multiply each sample by the previous sample.

Multiply digital numbers together? I'm not sure what we are trying to
achieve.

Normalize for amplitude
->(essentially the analog of a limiter stage).

Take the highest digital number and normalize all the signal samples to
that?

Run the output thru a
->lowpass filter to remove things above half the IF or so.

A digital lowpass or have you gone back through a D/A converter to get an
analog signal back?

There is a
->90 degree phase shift if the sig is exactly on 20kHz = fs/4, and the
->output is zero.

Why?

If the sig is above or below that, there is more or
->less than 90 degrees phase shift, and the output will be above or below
->zero.

Sounds like a digital discriminator. I'd really like to learn more about this technique. Got a reference that doesn't get too deeply into the theory and is more of a practical engineering cookbook?

>distinguish them?
> Dave KE9ED

Many people have described how to tell BNC connectors designed for RG-59 cable by the larger clamp diameter. However, these are still 50-ohm connectors being used on 75 ohm cable.

There *are* BNC connectors with a characteristic impedance of 75 ohms, and you will find them on some high-quality video equipment. You can identify them because the dielectric inside the connector itself is air, not Teflon. The physical dimensions of the mating parts are the same, so the 50- and 75-ohm versions will connect to each other. But the female 75-ohm connector has a bare center conductor socket without the usual Teflon cylinder around it, while the male connector has no Teflon cylinder just inside the ground contact barrel.

I guess keeping the conductor diameters the same but changing the dielectric to air shifts the impedance to 75 ohms. Of course, the voltage rating is reduced - but these connectors are used with 1 V signals.

The IC-2E is the European version of the IC-2AT.

>Also I want to know haw long I mus charge the batery and with wath charger?
>voltage? mA?

If it has the stock battery, a BP-3, charge at 40 mA with a constant current charger through the jack in the side of the battery. You can also bottom charge the battery with a BC-35 drop in charger. Icom also sold rapid charge batteries for this radio, BP-2, BP-8, etc. If you have one of these, you can charge at a much higher rate. The BC-35 will automatically sense what type of battery you've inserted and charge at the proper rate. Aftermarket companies still offer batteries and chargers for this radio. The same batteries also work on the Radio Shack radios.

You should be able to simply scale those plans, IE reducing every
dimension by 3 would yield a set of 432 MHz duplexers. To reach
440 MHz, you'd reduce everything by slightly more than 3.

Let's examine the Pathological Science in Rich's reply. We can learn something again (finally):

>The difference is that at HF there is a load. At VHF there is virtually
>no load. In a high mu triode, when there is no load, the grid current >is going to be astronomical.

Excessive grid current occurs whenever the anode's load impedance is higher than the optimum value at that operating point. This does NOT occur in a neutralized grid driven PA. As a matter of fact, grid current shift (when adjusting loading and tuning) is a good test for unwanted feedback in a grid driven PA.

In a grounded grid PA, grid current increases because the output and input are in series. That provides heavy negative feedback in normal operation. If tank impedance is increased, negative feedback is reduced. If tank impedance is reduced, negative feedback is increased. Exciter power contributes less to output and more to grid current (and heating).

This is why the gain of a grounded grid PA is almost totally dependent on the ratio of anode load impedance to driving impedance. With the same operating anode voltage and current, a tube with lower cathode impedance will have more gain. A 3-1000Z has lower driving impedance (~60 ohms) than a 4-1000 (~85 ohms), and hence higher gain. A 3CPX5000 has a 20 ohm cathode driving impedance, and will deliver almost 7000 watts in grounded grid with 100 watts drive with tha same anode impedance!!

While it is true that a PROPERLY loaded PA has normal grid current, high load impedance presented to the anode reduces negative feedback. The effect is exactly the same as increasing drive power.

Assume a tube with very high transconductance (like the 3CX800A7). If the anode is loaded for peak output (and normal grid current) with 50 watts of drive, and if the drive power is increased to 100 watts, most of the additional drive power goes directly into heating the grid!! Nearly 35
watts of additional grid dissipation occurs in this example!

If the drive is held at 50 watts and the anode impedance soars from an arc in an antenna tuner or antenna system, the effect is the same. Nearly ALL (~40 watts) of the original 50 watts of drive heats the grids!

The grid dissipation of a 3CX800A7 is 4 watts. Eimac determines this value by driving the grid with an AC signal while measuring secondary emission. When the grid approaches temperatures where material in the grid starts to fail from heat, secondary emission begins to climb. It's almost like watching the thermal runaway on a transistor!

At 4 watts grid dissipation, the 3CX800A7 shows the beginnings of destructive failure. Gold migration is rapidly accelerated if the tube is operated beyond this point. As a rule of thumb, at about two to three times the power where secondary emission climbs the grid will become incandescent. The gold plated tungsten grid will actually glow, and any gold on the grid will boil off.

Of course this is time related, since the thermal mass of the grid must be overcome. As little as 8 to 12 watts of dissipation for a few seconds can ruin a 3CX800A7. This power always shows up as grid current.

It's absolute non-sense to claim a 100 watt exciter can not damage a 3CX800A7 grid.

Moreover, excessive VHF current requires the tube is loaded with a high impedance, much greater than a few thousand ohms. If the HF tank presented such an impedance to the tube, any parasitic suppressor installed between the tube and the tank would do no good at all. In order for the suppressor to function, the tube to tank to ground path must be a low impedance. The very attainment of high VHF grid current would rule out the use of any suppressor! Once again Measures argues against his own claims. Once again the claims fall apart under examination.

Now consider this. Richard actually suggests people remove electronic grid overload circuits.

73 Tom

The only magic I have seen around here lately is the way people who no
longer work at Eimac can magicly be promoted and demoted. For instance,
the Chief Specifictions Engineer, Power Grid Division got demoted to
letter writer guy. An Engineer B got promoted to 'R+D engineering
manager' (whatever that is). Both actions took place years after they
left Eimac.

4165. RAPID CASH

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-21 00:00:00 UTC
From: Free Money <money@money.com>
Message-ID: <32BBAEED.7C6A@money.com>
Source record: 99411

This is the fairest, most honest way I have seen to share in the wealth of the world.!

Take five minutes to read this and it WILL change your life. If you want to know how to make thousands of dollars quickly, legally, and with NO CATCH, then keep reading.

The Internet has grown tremendously. It doubles in size every 4 months. Think about it. You see those 'Make Money Fast' posts more and more. That's ... because it WORKS ! So I thought, all those new users might make it work. And I decided to try it out, a few months ago. Besides, what's $5.00, I spend more than that in the morning on my way to work on coffee and cigs for the day. So I sent in my money and posted. Everyone was calling it a scam, but there are SO many new users from AOL, Netcom, etc. they will join in and make it work for you.

Well, two weeks later, I began receiving bucks in the mail! I couldn't believe it! Not just a little, I mean big bucks! At first only a few hundred dollars, then a week later, a couple of thousand, then BOOM. By the end of the fourth week, I had received nearly $47,000.00. It came from all over the world. And every bit of it perfectly legal and on the up and up. I've been able to pay off all my bills and still had enough left over for a nice vacation for me and my family.

Not only does it work for me, it works for other folks as well. Markus Valppu says he made $57,883 in four weeks. Dave Manning claims he made $53,664 in the same amount of time. Dan Shepstone says it was only $17,000 for him. Do I know these folks? No, but when I read how they say they did it, it made sense to me. Enough sense that I'm taking a similar chance with $5 of my own bucks. Not a big chance, I admit--but one with incredible potential, because $5 is all anyone ever invests in this system. Period. That's all Markus, Dave, or Dan invested, yet their $5 netted them tens of thousands of dollars each, in a safe, legal, completely legitimate way. Here's how it works in 3 easy steps:

STEP 1.
Invest your $5 by writing your name and address on five separate pieces of paper along with the words: "PLEASE ADD ME TO YOUR MAILING LIST." (In this way, you're not just sending a dollar to someone; you're paying for a legitimate service.) Fold a $1 bill inside each paper, and mail them by standard U. S. Mail to the following five addresses:

1. Michael Barratt - 27 Park Ave. - Poughkeepsie, NY 12603

2. Brian Truter - 101 N. Park Avenue - Springfield, IL 62702

3. J. Campbell - 1040 C Winners Circle - Bowling Green, KY 42104

4. Joost Walter - P.O. Box 259 - 2870-AG Schoonhoven The Netherlands

5. S. Thomas - P.O. Box 4945 - Tampa, FL 33677-4945

STEP 2.
Now remove the top name from the list, and move the other names up. This way, #5 becomes #4 and so on. Put your name in as the fifth one on the list.

STEP 3.
Post the article to at least 250 newsgroups. There are at least 19000 newsgroups at any given moment in time. Try posting to as many newsgroups as you can. Remember the more groups you post to, the more people will see your article and send you cash!

STEP 4.
You are now in business for yourself, and should start seeing returns within 7 to 14 days! Remember, the Internet is new and huge. There is no way you can lose.

Now here is how and why this system works:

Out of every block of 250 posts I made, I got back 5 responses. Yes, that's right, only 5. You make $5.00 in cash, not checks or money orders, but real cash with your name at #5.

Each additional person who sent you $1.00 now also makes 250 additional postings with your name at #4, 1000 postings. On average then, 50 people will send you $1.00 with your name at #4,....$50.00 in your pocket!

Now these 50 new people will make 250 postings each with your name at #3 or 10,000 postings. Average return, 500 people= $500.

They make 250 postings each with your name at #2= 100,000 postings=5000 returns at $1.00 each=$5,000.00 in cash!

Finally, 5,000 people make 250 postings each with your name at #1 and you get a return of $60,000 before your name drops off the list. And that's only if everyone down the line makes only 250 postings each! Your total income for this one cycle is $55,000.

>From time to time when you see your name is no longer on the list, you take the latest posting you can find and start all over again.

The end result depends on you. You must follow through and repost this article everywhere you can think of. The more postings you make, the more cash ends up in your mailbox. It's too easy and too cheap to pass up!!!

So that's it. Pretty simple sounding stuff, huh? But believe me, it works. There are millions of people surfing the net every day, all day, all over the world. And 100,000 new people get on the net every day. You know that, you've seen the stories in the paper. So, my friend, read and follow the simple instructions and play fair. That's the key, and that's all there is to it. Print this out right now so you can refer back to

this article easily. Try to keep an eye on all the postings you made to make sure everyone is playing fairly. You know where your name should be.

If you're really not sure or still think this can't be for real, then don't do it. But please print this article and pass it along to someone you know who really needs the bucks, and see what happens.

REMEMBER....HONESTY IS THE BEST POLICY. YOU DON'T NEED TO CHEAT THE BASIC IDEA TO MAKE THE BUCKS! GOOD LUCK TO ALL, AND PLEASE PLAY FAIR AND YOU WILL WIN AND MAKE SOME REAL INSTANT FREE CASH!

*** By the way, if you try to deceive people by posting the messages with your name in the list and not sending the bucks to the people already included, you will not get much. I know someone who did this and only got about $150 (and that's after two months). Then he sent the 5 bills, people added him to their lists, and in 4-5 weeks he had over $10,000!

>
> 73, Peter VK1PK

I use a small pi coupler mounted in a diecast box to match my 90 ohm
(more or less) RG62/U coax feeders to the 50 ohm antenna connection on
my 2 metre transceiver.

At the antenna - a 6 element yagi, I have used a coax balun matched to
the driven element at the appropriate point.

Why do I use RG62/U? Because I had a good quantity of it.

To set up the system, I terminated the coax balun with a 90 ohm set of
composition resistors (saved from the 1940s) and with an SWR bridge,
adjusted the pi coupler. Then I experimented with a stub match to the
driven element.

The pi coupler coil is about 3 turns of #20 gauge wire about 1/4 inch
dia. The capacitors are about 25 pF Johnson variables.

I hope that that helps.

73,

Jim, ZL2APE.

I missed the beginning of this thread but here is an idea for a simple fm receiver from a British magazine about 40 years ago: Pass the modulated rf signal thru a clipper to give square waves. Now thru a pipper (differentiator> to give pulses spaced at every zero crossing. (Keep only one polarity). Now integrate and you have a demodulated signal.

I am aware of only one person who was caught lying in this debate. One
person is not "everybody", and one person is hardly "everyone else", Mr.
Rauch. Is this a case of misery loves company?

"Criticism of everybody else in the world" certainly sounds impressive.
That's a lot of people. Who is criticising all these people Mr. Rauch?

I have found most of the participants here to be forthright individuals
who are interested in science.

IMO, any manufacturer of a 3CX800A7 amplifier who uses 15v on the heater,
who tells customers that 15v is perfectly okay (even through Eimac
specifications state otherwise) is incompetent. However, if you have a
different opinion, Mr. Rauch, I fully support your right to that opinion.

Try pressing down on the DSP chip. many times the chip will become loose in
the socket due to the heating and cooling of the DSP-2232. Also the DSP chip
could be in trouble.

The BP-3 is a 8.4 volt 250 mAh pack. You need to use a 13.8 volt source that is over 100 mAh to cjarge the battery. It takes 15 hours to reach a full charge.

Happy Holidays and thank you for reading this. I would like to buy a high-power linear amplifier that is well built and looks commercial. The power supply should be heavy duty and I would like the amp to cover 160-10 meters. 8877s, 3X500Zs, 3-1000Zs, or similar tubes are preferred. I'm sure someone has an excellent homebrew amp at a reasonable price. Thanks in advance for your reply.

HI Brian!

Well, quite simply get a hold of a program called COOLEDIT, it's on
the web, so you shouldn'T have any problems websearching it.

It allows you to generate Touch tones, or any other possible tones you
might want to generate. I used it to generate my FD's two tones to
test my minitor pager.

Hope this helps

Pat

I am looking for a couple lengths of B&W 3012 coil stock for
a receiver project. I know I could wind my own, but there are
4 interlinked coils in the project and I doubt I'd have a very
easy go of trying to get them all on the money.

It's 3/4" in diameter, 32 tpi. I know there must be some old stock
lying around out there somewhere.

If you have any you can part with for a price fair to all, email me
at:

Dave gekko95@ix.netcom.com

Many thanks in advance to any who reply.

Dave

The personnel department at Eimac's Salt Lake City plant told me that
Joseph Miklos was not the R and D engineering manager.

Does Reid Brandon work in engineering or does he work in marketing?

Hi Jim,

That circuit appeared in the GE Transistor Manual (I have my copy ,the 7th ed. 1964) It is on page 385 and has a note against the front end section which says: "Converter oscillates at one half signal frequency" You might have difficulty getting that past the CE and FCC assessments!

It has an AFC loop which can only work if the tunnel diode oscillates at signal +/- 200KHz or so. As you say there is no precise definition of the IF. The 300R antenna feeder couples via a 1:1 transformer arrangement so

high signal strength is needed and no isolation easily acheived.

Regards,

Like K1BQT, I'm another uninvolved observer, trying to sift and weigh the mountains of evidence in this long-running thread.

Rich Measures wrote, a few days ago:
> I phoned
>Eimac's Salt Lake City division at 801-972-5000. I explained what has
>been taking place in this debate. I said that certain claims about Mr.
>Miklos were being made in his absence, and that I would like to verify
>these claims.

Some written evidence is available here. According to the profiles of the authors in the ARRL UHF/Microwave Experimenter's Manual:

"Buzz Miklos... is currently the manager of R&D for RF cavities and tubes at VARIAN EIMAC in Salt Lake City, Utah."

Note that that the word "currently" in that quotation probably meant 1989-90, just before the book was published. Tom, W8JI did say that Mr Miklos has since moved on from that position and relocated.

If there is any inconsistency between the written record and information that some person at Eimac Human Resources gave out by telephone, we'll have to decide which source to trust more. Ask yourself: would anybody supply ARRL with false information about his employment position, knowing that it would be printed for everybody to see? (In most companies, "promoting" yourself into your boss's shoes is a severely career-limiting move.)

Again referring to the written record, by courtesy of Rich's own Web pages, the letter from Mr Foote of Eimac described the gold-sputtered tubes as:

"both have been badly overheated internally, the apparent result of an oscillation condition."

Note two things. 1. Mr Foote consciously decided to insert the word "apparent", implying a judgement rather than a statement of verifiable fact. 2. He did not say anything about the frequency of the apparent oscillation condition.

That letter was dated 1986, but it seems that Eimac staff no longer support Mr Foote's view. In QST for September 1994, Reid Brandon of Eimac opposed Rich's interpretation of the Foote letter. Although he did not say outright that "This is Eimac's corporate view," he did identify himself clearly, publicly and in detail as an Eimac employee. Would he then have stated views that his company did not support? (In most companies, that would be another career-limiting move.)

There seems to have been no further change in Eimac's position since
then.

Still sifting and weighing...

I have two high quality direct analog synthesis synthesizers for sale. These are Programmed Test Sources PTS160. They cover .06 to 159,999,999 in steps of 1Hz. They have the built in TCXO or can be referenced to an external source of 5 or 10 MHz. Power is AGCed and can be varied from about 0 to 16 dBm. Switching time is between 5 and 20 microseconds depending on the frequency. All the units have the rack mount and GPIB and parallel interface allowing them to be fully computer controlled. Spurious outputs are down -75dBc(discrete), -35dBc(Harmonics). Phase noise is -63dBc(.5 Hz to 15KHz),-105dBc (100Hz), -115 dBc(1KHz). Power is within 0.5 dB flatness between .1 and 160 MHz. Price is $550 shipped. Current price on identical units is around $7000. These units are surplus from used NMR imaging equipment and are in great shape. For more information please e-mail me. Thanks

Pieter Ibelings

I sell tubes to broadcasters for a living.

In the late 80's I had problems with some Eimac tubes. When I called Eimac they transfered me to the manager of tube engineering at Varian. His name was Miklos.

In 1990 I went to the NAB show. I met a ham wa4gpm who worked VHF DX. His name was Miklos and his card said R and D manager. He was there with John Button from Varian.

Bill Foote is in poor health now, he broke his hip. He is retired, but when he worked at Varian he handled answering customer return letters at Varian. Reid Brandon is a applications engineer, like Bill Orr was. Brandon and Button still work for Eimac.

WA9NVN, Mike

4182. HELP WITH BATTERY CHARGING

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-22 00:00:00 UTC
From: hq54@aol.com
Message-ID: <19961222040900.XAA10285@ladder01.news.aol.com>
Source record: 99428

Hi,

I need some helpwith a project. Recently I have been running a mobile repeater in my car off the car battery. After a couple months of use, the car battery began to die. It got to the point that after it running down a couple of times, the repeater would completely drain the battery in less than twelve hours. Of course, this was not good for my battery. Recently replaced it at a cost of $70.00 because if I stooped to get gas and shut off my engine, I could not restart. I'd like to get a battery and install it in the car for the repeater to use. I'v found some very inexpensive (the most important word here after upsetting the MRS. with the purchase of the new battery due to MY repeater, since the car, and battery, were only a year old) 12 volt 17 Ah and 24 Ah lead acid batteries. I need a way to charge the batteries quickly and safely. The other problem is that the car is rarely driven more than 20-40 minutes per trip. If the batteries only recieve a partial charge and then are discharged, will that adversly affect the batteris. Long term damage is quite insignificant as the batteries are just 10 dollars, but I don't want to have to replace them every week or month. Any help in a charger or suggestions as to better batteries, or even a different or better idea would be most appreciated. Please E-Mail me with the info.

Thanx advance for your help.

Mike

I have a Santec LS-202A VHF SSB/FM HT that I am trying to find a schematic for.
A service manual would be nice also, I would even settle for a owner's manual.

The unit receives properly, transmits properly, tx audio is good, rx signal is good,
rx audio is gone..... You can see the receive signal on the s-meter, and if you listen
very closely you can hear clear audio from the speaker, only very faint. I have bypassed
the speaker and replaced the audio IC, and now want to get some service info to go
further.

Any help appreciated, A current address for Santec or it's remains would also be a big
help. A copy of a manual and schematic would be a blessing.

Seasons greetings

Hi Rich,

At the end this will get useful again to people trying to understand PA's. I'm going to "assume" we can believe a few parts of your posting, and comment on them first.

In article <measures-1912960455060001@port29.vcnet.com>, measures@mail.vcnet.com (R. L. Measures) writes:
>About 14 hours ago I received a telephone call from Jim, KA3JSO. He >wanted to talk about designing suppressors for large amplifier tubes. We >talked for over an hour. During the course of the discussion, he told me >he once owned an AL-1500 amplifier. As you may recall from a previous >post on this thread, the AL-1500 uses no VHF parasitic oscillation >suppressor device. Jim told me that during the 12 month warranty period, >two 8877s failed suddenly. After 8877 number three was installed, Jim >sold the amplifier as soon as possible. Jim said that Ameritron told him >that the failures were caused by defective 8877s. Jim told me that >K20JL/V31BB had an AL-1500, in which a number of 8877s suddenly failed

It was probably V31B (not BB), a guy who eventually got electrocuted by wiring an external transformer into his PA to boost the voltage, that had the 8877 problems. I'm not sure if his PA was the fault of tubes, or his operation. He did operate it beyond our ratings by adding an external transformer. Unfortunately, the problem was self-eliminating. He came in contact with a bare wire on the exposed HV transformer, and someone eventually in his shack roasting away.

This is a good time to remind others that external transformers and power supplies are VERY dangerous. SO-239's and even the Millen HV connectors are NOT safe means of running HV around the shack. Both are idiotic.

During three or four periods of time in the 80's, Eimac had trouble with 8877's. That's what drove ETO out of the contract business with GE medical, they couldn't get reliable tubes either. I rememvber visiting ETO and discussing the problem with Ray Heaton.

The 8877's of that time were so unreliable, I built a fixture that would cycle the filaments of ten tubes (at a time) off and on. If the grid shorted to the cathode in any individual tube, a relay would trip and illuminate an indicator. Even though we weeded through tubes that way, we still had a high G/K field failure rate.

The problem was eventually traced to two causes, contamination of a material used in the tube and a heat dam problem. It was unfortunate, but Eimac was very good about warranty adjustments.

That problem nearly ruined sales of the 8877, and put ETO virtually out of the medical MRI business. People are still shy of the 8877 because of those 1980's problems.

>About 8 days ago, Marvin Born, KF8XU, telephoned me. He said he needed

>attempting to repair was producing intermittent VHF oscillations, as seen
>a a Tek 454 scope. Marvin said he could also see the intermittent VHF
>oscillations on a spectrum analyzer.

No, that is untrue. As I said before, that PA belongs to KC8MK. Marvin Born said you absolutley know better than to claim he said that, he very clearly told you the amp he measured the parasitic in was a 3CX3000 by Create Electronics or someone like that.

Of course when this claim is weighed along with your claims about Miklos and others, it is understandable why you say that. Sometimes you seem to present things as facts when they are not true. I assume it's because you are honest, but a little over enthusiastic in trying to support your theories.

Unfortunately Rich, your accusations that I was "lying" about Miklos appear to have backfired. It really is a poor idea to drag personal comments into a technical discussion, it just detracts from the issues. I suggest that we all forget all these little personal attacks, and just consider you made a mistake in your enthusiasm to support what you really believe is true. I'm sure you now regret implying I am a liar, and I am willing to let bygones be bygones. Anyone can make a mistake.

By the way, Jim Hurt said that PA (built from a prototype chassis I gave him) worked flawlessly for ten years until he plugged in a 1978 date code pull-out 8877. Then with the PA on standby, something arced over. I suspect the 1978 tube was gassy or had debris or gold deposits on the insulation inside. It's a good idea to use only tubes of known origin, and read the little dates on the tubes. The code date is a four digit number with yyww, 8822 would be the 22nd week of 1982. Stay away from 8877's made in the mid to late 80's.

>With the exception of Ameritron, all manufacturers of 8877 amplifiers
seem
>to use a VHF parasitic oscillation suppressor device. IMO, there must be
>a reason.

There indeed is. That PA is unconditionally stable without one. The grid ring is grounded to the chassis with finger stock, and the anode resonant frequency is many times lower than the self-neutralizing frequency of the tube, and the S21 parameters indicate complete stabilty with almost 20 dB of feedback headroom.

Here's something useful to consider.

The 8877 is used as a VHF PA in several designs. In those PA's, the anode is coupled to a resonant hi-Q VHF stripline WITHOUT any suppression. The

input is tuned to the same frequency as the output. These PA's operate with complete stability. This points out the weakness in Measure's claims that resonance indicates instability. Very plainly, it does not!

Of course we could NEVER use a 3CX1200A or D7, 3CX3000, or any glass internal anode tubes in an upper VHF PA. The most unstable tubes have large grid structures, and when the large grid structures are coupled to ground via long thin leads (as opposed to a cone) in the tube, stability is poor.

In a proper layout, tubes that make good VHF amplifiers are the most stable tubes to operate. Tubes that were designed for low frequencies (572B, 811A, 3CX1200A and D7, 3-1000Z, 4-1000A) are the most unstable tubes to use in any layout.

One excellent example of this is the 3CX1200D7 when compared to a 3CX1200Z7. The Z7 uses a grid flange instead of long ribbons that connect to the pins. A Z7 is useful at two meters, and unconditionally stable on HF without any suppression. The very same tube, without the grid flange (the D7), is very difficult to stabilize at HF.

Get a copy of TELIX (shareware). Although designed for telco links it is
excellent for ham radio comm purposes - has most of the bells and
whistles and is a DOS program that will run well on the older computers.

Another solution is the use of radio controled airplane-boat servos, motors and radio transmitters. Thats kind of what they do. You push a button, and the motor on the other end is activated and moves an arm that controls something. I do not know what the cost may be. Worth checking out.

I have two buddies who both own the Pro51, They both like it. Only
problem is, RS changed the pro51 in mid production to include and
permanent cell block. The earlier version only needed a keyed sequence
on the pad.

Already the days are not as bright as before. It seems that the light is failing, and the brooding, heavy clouds are completely covering the sky as the thick fog wells up from the dank, cold, nether regions of the earth. Tonight, in the early morning hours, between midnight and 4:00 a.m., while you lie in your "secure", warm bed---hold your breath and listen ever so carefully. "Outside in the cold distance", the faint soul-chilling howl of the slowly approaching demon can already be heard! If not by some "miracle", science and logic will soon be devoured and torn asunder by this monster of ignorance and superstition. And, the light of knowledge and learning will forever be extinguished.

Yesterday we lost a great man of science and the scientific method. We lost an exceptional teacher, not only to the students who were lucky enough to attend his varied classes at the university, but an exceptional teacher who could teach the "masses" the most complicated and exotic theory of physics, astronomy, cosmology, etc. with the ease of teaching first grade math! A man whose "magical" speaking voice could transport any and all of us, spellbound, to another star system or galaxy--or even another dimension, and we could actually see and feel the far distant surroundings. We lost "the pride of American science", a good and moral man, the likes of which we will probably never see again in this country, where the disciplines of the sciences are fast losing ground in our present decaying educational system.

If we would honor Dr. Sagan, and wish to leave a memorial to him and what he stood for, let us not forget the "kind" of science he believed, lived, and taught----The science of Einstein, Oppenheimer, Hawking, Chandrasakar, and their fellows. The REAL science!

Though he never lived to see the turn of the century, nor the verification of the elusive extra-terrestial civilization that he searched for with every fiber of his being for so very long, let US continue the search with a vigorous, new campaign. Let us all signal our respective congressmen and senators that this search is the single most important quest on which mankind has ever embarked! Our very existence may very well depend upon the success of such a search, and our place in the universe most certainly does!

I have read a couple of posts that indicated maybe it was fortunate that Dr. Sagan was no longer with us. I dismiss these with the thought that the posters have no real knowledge of the Dr.. It's true, to some he may have been a "debunker", but if pseudoscience, ignorance, and hoaxes

aren't debunked, then people, we are inviting the demon of darkness right into our personal world.

If, and I say a big "if", there's life after death, then we now have one of the very best researchers, ever, on it--- full time! Goodbye, Dr. Sagan.I will miss your sane analysis in an increasingly insane world.

Respectfully,

Joe Bryan Clark, kc5itc

I am looking for a couple lengths of B&W 3012 coil stock for
a receiver project. I know I could wind my own, but there are
4 interlinked coils in the project and I doubt I'd have a very
easy go of trying to get them all on the money.

It's 3/4" in diameter, 32 tpi. I know there must be some old stock
lying around out there somewhere.

If you have any you can part with for a price fair to all, email me
at:

Dave gekko95@ix.netcom.com

Many thanks in advance to any who reply.

Dave

Check with TAPR, the originators of the tnc now known as TNC-1 and the
TNC-2. They may not still offer it, but a few years ago you could get
the schematic for the TNC-2 from them for a few dollars, and you could
also get a circuit board and/or the ROM.

I don't have the TAPR address handy. I think their web page is
www.tapr.org
but if that doesn't work, use one of the search engines.

Rich is correct here IF (big if) his information is accurate. I've seen
this problem in some PA's, but I have never measured (no pun intended) a
Command PA or a Henry.

I can't speak for Richard's claims in those cases, but if it is true the
manufacturers should be VERY concerned about correcting that problem.

>You are only guessing until YOU make the measurements, Tom. I made the
>measurements. I wrote about them in "The Nearly Perfect Amplifier" in

This is a well known fact...the problem was so bad that a procedure was
set up between Eimac and GE Medical to specially select 8877 tubes to be
used in GE MRI machines. The "selection" criteria is a gray area at the
moment, as Eimac has refused to answer my inquiries about the process.
This is obviously done at the Eimac factory before delivery to GE and its
MRI amplifier suppliers. In the late 1980's, after the "selection" program
began. 8877 tubes appeared on the market (even as OEM units in Alpha amps)
that were in plain brown boxes with blue labels marked "Industrial Tube".
The tubes themselves were no longer labeled 8877, but "YU158". This process
continues to this day. I suppose GE and ETO do not intend to get stung again!
If you inquire at Eimac, they will tell you the YU158 is a "selected" tube,
and is completely compatible with any 8877 application. I have tested several
YU158's, and my experience is that the tubes put out the same power as the
8877, but with slightly less plate current, much less grid current, and
therefore less exhaust plenum temperature.

snip....

(G4BXD,106312,1035@compuserv.com) posted a message to
rec.radio.swap (8 dec 1996 16:57:51 GMT) looking for Command set bits
and
pieces. I tried to respond but cannot reach your email.
I tried using the Ham Callsign search servers but couldn't find
you listed there either..

This is what I have. All responses welcome.
I have a command set - R-27/ARC-5. It's got the following six tubes:
Tube Nr. Condition
12SK7 - good
12SF7 - good
12V6 - good
12SQ7 - good
12SK8 - Unknown*
12SK7 - Bad**

*TV-7D/U nor the Simpson Model 1000 tube tester has setting to test the
12SK8.
** One of the 12SK7 Tubes is bad.

The cabinet is still intact, but it's missing the lid(?) that goes on
top over the tube compartment, and there is no dynamotor. The inside is
clean - no burned parts, etc. Don't know if it works or not.

The whole thing weighs 7 pounds.I'm asking $45.00 plus shipping and
handling.

I also have two of the large three-ganged variables from a couple
of Command sets that were parted out. I am asking
$5.00 ea + shipping and handling.

I've another R-27 chassis with caps, a few Coils,
and the varible condenser tuning unit and dial.
$8.00 + Shipping and handling.

Will sell or trade 4-1000A RF Deck complete. Set up for 80, 40, 20, 15 and ten. Vacuum plate and load tuning. Tuned input, full output tube and SK406 chimney. Has switch installed accomidate either 4-1000A or 3-1000Z. Meters and power line all filtered. Deck is 17W X 17D X 16H. The front panel is 19 X 17 this fits inside of a cabinet about two inches larger in all directions. I also have a optional supply capable of 4.5 KVDC @ 1 amp. The supply needs some work. The variac presently in the supply is to small in current rating. I have the replacement units for the supply. The RF deck is fully metered plate amps, plate volts, grid current and rf output volts. Asking $550.00 for the RF Deck and 225.00 for th supply and new 20 amp variacs. Thanks Jerry W0ZD.

Andy

I would have to disagree with this statement. The assumption being
the "non-oscillating amplifier" would be properly tuned and loaded
and the tube operating within rated specifications.

In a VHF "oscillation condition" what mechanism exists to provide
a proper load for the generated VHF RF energy in an HF
amplifier? What would limit the tube's dissipation, or RF voltages?

Humm. Well as I said before there is a program "called" Circad on a CD rom. This is not the Circad that I'm talking about. Of course I don't know which one you are talking about. I honestly think you have that other program as I think Circad (the real one) is a pretty good program. Nice, easy to use and fast. How many programs are written 100% in assembler now aways?
I have some friends who use it on 386 and even 286 machines. The autorouter runs faster on these old junkers than other programs run on current speed demons! But that takes us into the world of Bloatware <grin>. As to the points on ease of use the entire manual is online in HyperText. Of course you get a nice written one if you buy the program but it IS nice to be able to look up things when the manual is stuffed under a pile of books. Everything is menu driver. With those Windows type menus that you mentioned. One point about Circad I perfer is that all the functions are also keyboard-able. This way you can touch type designs as well as pointing and clicking. The mouse is great when you don't know the commands but once you pass that you can really fly! I've done a good pile of PCBs with Circad and I've come up the ranks with the "other" programs as well. I like Circad because it addresses the shortcomings of so many of the other programs. Sure OrCAD SDT was ok in its day. I don't think any of the programs I used (and there were a few) went from A-Z well at all. And all of the PCB programs were pretty sad. Today it is not enough to have a good PCB program or a good Schematic editor. You have to have both to make it science not art. Otherwise you spend too much time manualy verifying connections and that sort of rubbish.
If you do get a chance check and see which Circad you have. If you have the Holophase program that I guess we have to agree to disagree. I suspect from your comments that it is the Qbasic? (or some other rubbish) thing I saw on one of the Sharware CDROMs.

I'd almost forgotten about this, but my brother-in-law and I were talking about whiskey and swimsuit calendars when suddenly he remembered something.
"I've got an old radio you gave me years ago. You want it back?"
"Sure," says I, dumber 'n a post.
So after we looked at the swimsuit calendar (it was a Yule gift from his uncle...), we got the radio out of the box.
Now I have in my paws -- dust and all -- the Lafayette HA-600 receiver that I'd bought off of Chuck Gelm (amateur call garbled in transmission over time) for $5 one year when I was sober and Chuck weren't. What a trip.
First, I'd forgotten how fussy rotary switch contacts can be. I have to jiggle every knob a couple times back & forth to get anything to come out of the headphone hole. And it ain't all that great at workin' either. But the real shocker to me was opening it up again, after all these years, to discover that it's only got one little circuit board inside. Like some sort of AM radio on a chunk of bakelite(tm) in the back of this anodized, folded by a punch-press, heavier-n-me chassis & box. I mean, this sucker is a monster next to my ICF-SW7600G.
Heck, even the ICF-SW7600G has more letters in its name!

Whaddya think it's worth? At the Dayton flea market, I mean. And yes, I'm serious. There's gotta be a demented, decerebrated-frog-type radio loonie out
there somewheres what wants this piece of RADIO HISTORY(!!!![trumpet fanfare
in the background as the dragsters rev up]!!!!!)

This describes a function. There won't be any diodes labeled "clamping diodes" on your dealer's shelf.

The term might describe many things. For instance, a common function is to clamp (limit) the reverse voltage spike generated in a switched inductive load (such as a relay) when the current is turned off. A transistor switch in this case might be destroyed by the reverse polarity voltage applied to the collector. The diode across the coil limits this voltage to approximately .65V and saves the transistor.

I have a Icom 775DSP and a Icom 706.
Both have the acc. Plug # 1 and 2.
I am using pin # 3 of the acc #2 to switch my amplifier (with the Ameritron ARB-700 relay buffer)
using pin # 3 of acc plug1 to swath the radio TX on and off from the computer via a level converter.
I am using this future for RTTY (I am using RITTY by K6STI)

Here is the problem I am having.
As soon I connect acc plug #1 (the one from the computer level converter) the amplifier switch on, it does this even with the level converter disconnected from the computer.

I also have tried a different relay buffer for the amplifier but the same thing happens again.
So far I have tried anything I could think of an no result (It drives me nuts) I even build a second level converter.

Any help would be appreciated.
Thanks 73 Will, KN6DV

Good point, Peter. I have seen large air gaps arc for no apparent
reason. An arced TL-922 tune capacitor is currently being shipped to me
from NM for testing. I will test it and post the results here. When this
tune capacitor was replaced with a new unit, it also arced. IMO, the
mysterious intermittent arcing is VHF parasitic related. The owner of the
amplifier, David Holtcamp, K5KH, is currently trying to arrange for having
the amplifier tested with a spectrum analzer at the lab where he works.

For sake of argument, I downloaded CirCad from the Holophase BBS. I tried to
get it from the WEB site but the copy was corrupted.

What I unzipped was the not exactly like the one I had previously tried. The menus were still crummy. Just like I said before they look as if a beginner made them. The look of the program seems like it was made at least 10 years ago. Just like I said before.

When I said not exactly, I did find a few things were changed. Your library are a little fuller of components and other symbols. Would that be the highly touted work you added to the program?

I also noticed another change. The version I had, and I'm still sure it was from a shareware CD-ROM ; NIGHT OWL I think, was a demo with a preset time period. I could defeat that by setting my CPU date back to the date of the program. Everything was renewed. The time limit I mean. Seems like ya'll corrected that. Would that be why you don't support or recommend the shareware version?

Well anyway you are wrong about the learning curve for CirCad. It is steep!

Oh...answer my question about how you get over $700 off the cost of the program.
Details are Okay. I got time. That is 70 % of the cost....

There are freeware programs out there that are a whole lot easier to learn. Anyway hams can get construction PCBoards and layouts from the author of most homebrew projects. 1 of 1000 hams, maybe, experiment in radio design. CAD
ain't no household word yet.

Mine still works fine. I use it occasionally.
I might take $100 for mine. Maybe before I add a frequency display to it.
I really enjoy using old analog SW receivers. During my childhood we had
those big console radios that stood five feet high and lit up like
firworks when they were on. I loved to set in the dark and tune in the
world dreaming about those far away places and was amazed at how the
signal got here from there.

THE COMPLETE RF TECHNICIAN'S HANDBOOK

(Published by Howard W. Sams, Inc.)

"The Complete RF Technician's Handbook" is THE book for the radio communication's beginner, student, or experienced technician, and supplies priceless information on not only wireless fundamentals, but also the advanced concepts vital to a successful career in RF communications.

Included are over 400 informative ILLUSTRATIONS and tables

The handbook includes everything a technician needs to know in real-world RF electronics -- from the fundamental concepts to the more advanced explanations of modern ANALOG and DIGITAL RADIO circuits and modulation methods. Furthermore, operational instructions on RF TEST EQUIPMENT, as well as identifying proper and improper signal waveforms, and AM, FM, PM, and SSB theory are included. In addition, transmitter and receiver testing methods and TROUBLESHOOTING TECHNIQUES are solidly covered.

>12SK8.
>Greg
>KB6WKW

Greg,
You would have better luck if you looked at the tube tester's entry for a 12K8 (the 12 volt equivalent of the 6K8 converter/oscillator tube). That's probably why you didn't find it in the list. The tube has a grid cap on top; ergo, no 'S' in the name. The 'S' denoted 'single-ended' tubes that had no grid or plate caps.

Hope this helps.

measures@mail.vcnet.com (R. L. Measures) wrote:

> So how do we figure total Q when
>the parallel Ls contains series R of its own?
>
One perspective is to convert the parallel resistance to its equivalent series resistance and then calculate Q as XL/RS', where RS' is the new total series resistance.

The result I get is :

Q= XL/((RS(1=RS/RP)+XL^2/RP)

where XL is the inductive reactance, RS is the actual series resistance, and RP is the actual parallel resistance.

Note that if RP goes to infinity the Q goes to the usual expression, XL/RS.

And, if RS goes to 0 the formula goes to RP/XL, which s also correct for that condition.

In general, Q is 2*pi*frequency*stored energy/power. For a complicated circuit, just compute the losses (power) and the stored energy in either the inductive part or the capacitive part of the circuit (they are equal.) This works for trnasmission lines or any circuit whatsoever.

One interesting technique that no one has mentioned in this lengthy "discussion" is the pertrubation method. Ypu can determine the equivalent circuit at any pair of terminals quite simply. First measure the resonant frequency. Then add a known capacitance across the two terminals in question. The change in frequency is delta f. The change in capacitance is delta C. Since delta C over C = - 2 delta f over f for small changes in frequency and we know f, delta f, and delta C, we can calculate C=- (f*delta C)/(2 * delta f).

Now we can calculate the equivalent L at the terminals. To get the resistance, measure Q and calculate Rp=XL * Q.

Now, if you want to know what the impedance transformation is betwen any two pairs of terminals, measure delta f at two places and calculate the corresonding equivalent C's. The impedance transformation is just the ratio of the two capacitive reactances. If you use the same delta C both places the impedance ratio is just the ratio of the two delta f's. The low impedance side is the one with the smallest delta f.

Lots of useful information, no network analyzers required. This works for any resonance in the system, HF or VHF. Warning: The accuracy can be affected by the inductance of the perturbing capacitor.

If you don't have a reasonably well known capacitor, you can use a short length of coax or twin lead and estimate its capacitance, knowing the properties of the coax or twin lead.

The principle requirement here is a way to measure frequency reasonably accurately, a calibrated signal generator or frequency counter are best. Grid dip meters are pretty inaccurate, bumay do for crude estimates.

Right, I know that, Tom, but the 1/4-wave peaks (such as they are) do
fall out to those dimensions. A "groundplane" is never really ground.
That's always a single point, whether you intend it to be or not. And
for tubes with a grid flange, the path to that point is so short that
resonances at VHF are practically impossible for a grounded grid
configuration. (I'm sure you know that.) The problem comes with tubes
with long skinny internal leads. (I'm sure you know that too.)

4226. QST AUG-96 2mtr notch filter"L1"?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-23 00:00:00 UTC
From: kovar@zeus.ia.net
Message-ID: <59mbsq$rhj@hera.ia.net>
Source record: 99522

QST has a great article in AUG 96 page 42 for building your own

notch filter for 2 meter pager inteference problems.

My problem is that I have not been able to find discribed value for L1.

Should I just use the formula for series resonant circuits and put in a

value of 1 to 14 pf for C2?

I have a box of bidirectional couplers with a male to female N connectors.

SMA sampling ports are dented.

A dandy box for this project if anyone is interested in one.

ANYWAY if someone would care to throw a value at me for L1 I will run

and check my math.

Thanks,

Jack Kovar

From: kovar@zeus.ia.net
Message-ID: <59mctu$rhj@hera.ia.net>
Source record: 99523

I have a MIRAGE B3016 2mtr amp/preamp that is giving me fits.

I seem to have a bad FET U309 "metal case three legs".

Diagram in book discribes it as a JFET J310 or U309.

I crossed J310 with a NTE326 or ECG326, Three legs plastic JFET.

Sound great right! Part is discribed as P channel General purpose

AF AMP. I know my hearing range won't make it to 144mhz.

Circuit is S is grounded, G is input with 120 ohm to ground,

D is output with .15 ohm and +13.6 vdc.

ANY ideas ?

The ECG/NTE shoots the top off like pinball machine!

Thanks,
Jack Kovar

Source record: 99524

Hi Peter,

In article <19961222212000.QAA26102@ladder01.news.aol.com>,
commquart@aol.com writes:

>I would have to disagree with this statement. The assumption being
>the "non-oscillating amplifier" would be properly tuned and loaded
>and the tube operating within rated specifications.

I can't speak for Andy, but there is no difference between the voltages and currents induced by self-excitation and those induced by excitation. If I looked at a tube that failed, I would have no idea what caused excessive dissipation of breakdown of an element, unless I found a abnormality in the mechanical construction of the tube.

This is the reason Eimac had such difficulty curing the 1980's problems in the 8877.

>In a VHF "oscillation condition" what mechanism exists to provide
>a proper load for the generated VHF RF energy in an HF
>amplifier?

I tried to cover that, but it may have been lost in the effort to avoid the pathological bullets being fired. Let me try again.

Let's assume we have a properly constructed tube. Short of mechanically damaging the tube by external forces or excessive peak emission current in a metal oxide cathode, the only thing that can permanently damage the tube is heating of materials used in the tube. This is true of everything from inrush failures through grid damage to melted glass. It's all heat, and the heat is only caused by current flow.

If the tube arcs, the damage caused by the heat of the arc. If the grid evaporates gold, it is caused by heating of the gold. If the glass melts, it is caused by heating of the glass.

There is one thing that is very important to remember. If the time is long enough and energy high enough to cause damage to the large thermal masses inside the tube, the cause of failure is always detectable outside the tube. There are no mysterious ghost-like things that damage the tube without indications on a meter. If it is inrush, you can measure it. If it is grid current (from an intermittent oscillation or excessive drive) you can probably see it on the meters and CERTAINLY detect it and remove the cause with an electronic overload system. It takes time to heat things, so damage is a function of the amount of overload and the length of the overload.

For example, a filament can take 1000 % overload over and over again if the duration is so short that the thermal mass of the filament is able to absorb the heat. It is the DURATION of inrush plus the amount that causes the problems, not just tyhe fact there is inrush. Assume we have an inrush of 30 amperes in a 15 ampere filament 3-500Z for two minutes, we know that would be damaging. If we have an inrush of 100 amperes for one half cycle of 60 Hz AC, it would be virtually harmless.

>What would limit the tube's dissipation, or RF voltages?

To repeat an earlier point, if the tube oscillates the anode impedance would likely be high, the feedback path capacitive, and the grid in a high impedance mode at that frequency. It would be a TPTG oscillator, or at least a TG oscillator. The gain of a grid driven stage (as this would be) is dependent on the ratio of a divider comprised of the anode to ground shunt impedance, the anode to grid series impedance, and the grid to ground driving impedance.

When the grid draws current, the impedance of the grid circuit falls through the floor. This limits the gain. If the amplifier is on the edge of oscillation, feedback falls below the level required to sustain an increase in output, and the stage limits. The anode impedance also falls with increased plate current. Both of these mechanisms work to limit the peak voltages and currents during oscillation.

This is the very reason why self biased LOW mu tubes are used in self-excited oscillators. If the mu is low, feedback can be set much higher and the tube bias resistance set to provide optimum drive current over widly varying loads and tuning conditions. The feedback is closer to unity and only the self bias limits the current.

A conventional high mu triode would fall in and out of oscillation if used in the same circuit.The hoax of a high-mu (or any) tube being stable almost all the time and then suddenly exploding from an oscillation is exposed once this is understood.

Hi Phil,

Thank's for confirming something that is very important. And Ian, thank's for point out Miklos' profile in the book. I have a letter on the way from Eimac's Personnel department since I don't enjoy being called a pathological liar, but that issue is completely resolved now with both your and Mike's comments.

I'd like to focus on important areas highlighted by Phil's comments.

I hope time spent here corrects damage done to people trying to learn how PA's work.
The tragidy of the false claims presented by only one individual is they hurt many people trying to learn. That is a crime far worse than calling me a name, and one I find totally unforgivable (if intentional).

In article <59jt54$hip@dallas1.connect.net>, philk5pc@connect.net (Phil Clements) writes:
>In article <19961222062700.BAA13068@ladder01.news.aol.com>, w8jitom@aol.com

>>8877's.
>
> This is a well known fact...the problem was so bad that a procedure was
> set up between Eimac and GE Medical to specially select 8877 tubes to be
> used in GE MRI machines. The "selection" criteria is a gray area at the
> moment, as Eimac has refused to answer my inquiries about the process.
> This is obviously done at the Eimac factory before delivery to GE and its
> MRI amplifier suppliers.

The problem was unclear because it was complex in cause. Eimac worked hard to solve the problem, and they did. Service history indicates current 8877's are virtually free from these problems.

(The failure displayed itself as a sudden grid to cathode short in the 8877.)

Unfortunately, while manufacturers were busily working working with tube design and manufacturing process engineers to solve the problem, one individual was using a platform in QST to give completely false data to users. He was on the outside of everything, but he was telling everyone manufacturers were lying (thank goodness I was not alone on the liar-list, hi!) and the cause was parasitics. He single handedly set back the cure of the 8877 by stopping the free exchange of information between

customers and manufacturers. He caused customers to believe Ameritron and others were lying about problems, when customers were actually being given the full truth.
Eimac would replace the defective 8877's and WANTED to get defective tubes back, Ameritron wanted to get any PA with multiple failures back in untouched condition, but someone was busily convincing customers to not co-operate. Instead of a team working together, amateurs refused manufacturer's help. Instead of no-cost repair, customers sent money to the fellow on the outside with all the answers.

When customers found a tube that finally worked, Eimac couldn't trace the batch. Customers thought the "cure" was the chicken claws and bag of bones the shook over the amplifier, when they really just finally got a tube from a good batch.

Eimac couldn't trace the batch. Customers paid for tubes they could have gotten for free, and we all were losers... except one guy.

>In the late 1980's, after the "selection" program
> began. 8877 tubes appeared on the market (even as OEM units in Alpha amps)
> that were in plain brown boxes with blue labels marked "Industrial Tube".
> The tubes themselves were no longer labeled 8877, but "YU158". This process
> continues to this day. I suppose GE and ETO do not intend to get stung >again!

Even the selected tubes were no sure cure. The problem was eventually traced to a getter and heat dam problem. The suspicions ranged from air pollution at Salt Lake City (Eimac was trying to tie batch failures to the air pollution index during the manufacturing process) to material and assembly defects.

> If you inquire at Eimac, they will tell you the YU158 is a "selected" tube,
> and is completely compatible with any 8877 application. I have tested >several
> YU158's, and my experience is that the tubes put out the same power as the
> 8877, but with slightly less plate current, much less grid current, and
> therefore less exhaust plenum temperature.

That is true, because the batch selection process guarantees closer tolerances in performance.

People should NOT be afraid of new 8877 tubes, but they should avoid buying used 8877 tubes from the 1980's. Penta Labs was also somehow obtaining and relabeling bad batch 8877 tubes as new tubes "made in China". Use only current code date 8877 tubes made by Eimac, with the stamped in logo.

Some defective tubes never made it back to scrap piles, and are still sold as surplus 8877's. Some old tubes are even out with new plating and labeling, a fellow in California (*not* Richard Measures) actually spent some time in jail for relabeling and selling used tubes as new tubes.

The less than honest behavior of individuals out to make a buck on people's problems hurts all of us. I hope the time spent here by everyone steers us away from magic and voodoo, or as someone coined (a name I like much better).....Pathological Science.

Have a Merry Christmas, and a Happy New Year!

Tom

>
>Understand. Mix it with an LO that is close to the desired. One small
>problem is desense of the RF stage with the LO, but that is an RF problem
>and not a digital one. That I can handle.

The bigger problem is the nearby image. That's tough to deal with in a
tunable design.

>-> digitize it
>
>in what sense digitize? Sample at some higher frequency than the IF and
>recreate the IF frequency as a bunch of analog dots? I honestly don't
>understand what it means to digitize an analog signal other than sampling
>and recreating the same analog signal as a whole potful of digital levels.

Ok, to digitize an analog signal, we sample it at or above the Nyquist
limit, IE with a sample repetition rate at least 2x the highest frequency
component of the signal being sampled. Nyquist showed that you can fully
represent a sinewave by two or more measurements made per cycle. (Any signal
can be represented as the sum of a series of sinewaves.) These samples are
digital numbers representing the voltage of the signal at the time the
sample is taken.

The sample window is very narrow, as close to zero width as you can get,
so that it represents the true instantaneous value at the time the sample
is taken as closely as possible. This is usually done with a sample and
hold gate. The A/D converter can then convert the sample into a number,
taking as much time as it needs to do so as long as it is done before
the next sample must be taken.

The number of bits used to represent this number determines the dynamic
range of the system. 8 bits can represent 256 levels (counting zero),
so it yields a voltage dynamic range of 48 db. A 16 bit word represents
65537 levels (counting zero), so has a dynamic voltage range of 96 db.
A/D converters with more bits of resolution typically run slower than

A/D converters with fewer bits, so there's a practical limit to how fast
the sample repetition rate can be for a given resolution, IE how high
the frequency can be that you are sampling.

A HF receiver faces a signal environment with a dynamic range of up to
160 db or so. Therefore even 16 bits aren't enough to fully preserve
that range, but an A/D with enough bits that's also fast enough isn't
yet available at a reasonable cost. You can slide the zero reference
up or down so that the A/D "windows" only a part of the full range,
and this is often enough. This is a truncating form of AGC. You can
also use more typical analog AGC on the analog RF front end stage of
course.

Ok, what you wind up with is a series of numbers, each made up of
a number of bits that depends on the resolution of your A/D converter,
and coming at a rate equal to the sample repetition rate, IE at least
2x the highest frequency in the signal you are sampling. This is the
digital equivalent of the analog signal, and you can now process it
with mathematical functions which are the equivalent of analog processes
such as amplification, filtering, mixing, etc.

>, and process it
>->with an algorithm which is very similar to an analog quadrature detector:
>->just convert to, say, 20kHz IF, digitize at 80k samples/second, and
>->multiply each sample by the previous sample.
>
>Multiply digital numbers together? I'm not sure what we are trying to
>achieve.

Multiplying two digital signal streams is equivalent to running two
analog signals through a mixer. What you get from multiplication is
a *product*, just as what you get from an analog mixer is a *product*.
And theory shows it is the *same* product in each case if you've dotted
all the i's and crossed all the t's in sampling to generate the digital
signal streams.

> Normalize for amplitude
>->(essentially the analog of a limiter stage).
>
>Take the highest digital number and normalize all the signal samples to
>that?

Since you are only interested in changes in phase, IE d(cos(wt))/dt,
you want the amplitude to be the unit vector. Normalization accomplishes
this. Though I have a question for Tom. Don't we want to normalize *before*
multiplying too?

> Run the output thru a
>->lowpass filter to remove things above half the IF or so.
>
>A digital lowpass or have you gone back through a D/A converter to get an
>analog signal back?

It depends on how accurate a LP response we need. For an accurate
response, we'd do it in digital and then use a simple RC reconstruction
filter at the analog output. If we don't need a very precise LP function
(and we don't here), we can depend on just the RC reconstruction filter.

> There is a
>->90 degree phase shift if the sig is exactly on 20kHz = fs/4, and the
>->output is zero.
>
>Why?

We have cos(wt[i])*cos(wt[i-1]]-pi/4). If there is no frequency change
between sample i and sample i-1, the product will be a constant, IE
a DC level. If there is a frequency difference, the product will vary
over time, IE our modulation envelope. What I don't see here, however,
is detection of this envelope. We need to take the absolute value of
the product to recover the actual modulation waveform.

> If the sig is above or below that, there is more or
>->less than 90 degrees phase shift, and the output will be above or below
>->zero.
>
>Sounds like a digital discriminator. I'd really like to learn more about
>this technique. Got a reference that doesn't get too deeply into the
>theory and is more of a practical engineering cookbook?

Humph. You have to understand the modulation theory in mathematical
terms before you can know what functions to perform digitally to
get the desired results. So any text that treats this subject has
to get somewhat deeply into signal and modulation theory for discrete
systems.

My constant reference is _Digital Modulation and Coding_ by Stephen G.
Wilson. Now I'm interested mostly in digital modulations, of course,
but Wilson is clear enough and general enough to be used to understand
the process with analog signals too. This is *the* most lucid book I've
found on digital processing and digital signal design and coding.

A more general book is _Digital Communications Techniques, Signal Design
and Detection_ by Simon, Hinedi, and Lindsey. But that thing is a drag to
wade through. Don't use it as an introduction.

Some other books which may have more application to digital processing
of generic analog signals are:

Digital Signal Processing, A Practical Approach by Ifeachor and Jervis
(lots of people like this one)

Analog and Digital Signal Processing by Ambardar
(and this one)

Modern Signals and Systems by Kwakernaak and Sivan
(I like this one)

Digital Signal Processing by Roberts and Mullis
(dry, dry, dry)

There are also a number of "cookbooks" on the market. And several of them are very useful. However, they assume you have the background necessary to know *why* you are executing the recipes they offer. So you really need to read some more theoretical books first.

Like the Energizer Bunny, new charges and claims against the amateur industry to support the sales of a small after-market company could grind forth with tedious repetition until everyone who even remotely cares may stop challenging and go away in a state of dazed disbelief or fatigue. On the other hand, perhaps the new year will be kind to all of us and this hideous thread will go away. I, for one, am totally convinced that Rich's claims have been proven sufficiently "incredible" to dismiss. But, as honest Abe said, "you can fool some of the people some of the time". And. perhaps that's often enough to keep the ole' bunny hopping!

No. The insulation material is aluminum oxide (ceramic).

> The same dangerous stuff used in RF power transistors?
>

Opening such tubes involves breaking nothing. I hold the kaput tube is a
vice. Using a fine tooth coping saw, I barely cut through the sheet metal
flange that is silver-soldered to the ceramic anode insulator. One must
be careful not to let the saw blade penetrate more than a couple of mm
into the interior, or the grid cage could be damaged.

The tube in the photo was driven so hard that a short circuit developed
between the cathode and the grounded grid---yet no gold-sputtering damage
to the grid occured. How is it possible to drive a shorted tube hard
enough with HF to cause gold sputtering.

This afternoon I tested David Holtcamp's TL-922 tune capacitor. The
breakdown voltage was about 6100V. David observed that this capacitor
arced during operation on the CW tap. The HF voltage present on the CW
tap is around 2000V IMO, the intermittent arcing of the 6000v+ tune cap.
was due to a largely-unloaded VHF parasitic oscillation.

The NWS WX receiver uses a 1050 Hz tone to activate. S-Com repeater controllers are easily set up to send this frequency tone. I have thought about doing the same conversion here in Paoli, IN. But so far have not had enough takers in the club.

In Radio Shack's 200 in One electronic project kit there was a circuit for a "spark" transmitter that used a relay, an audio transformer to step up the voltage, and a coil and capacitor to tune to the AM broadcast band. This little transmitter could be heard a number of feet away as it sent morse code. I remember building this on the spring-coil board in the kit and it was fun . (I was in Jr. Hi. at the time.) I think the circuit is still in the project kit.

Good luck.

Comet and Diamond make units such as this for 80 bucks....

I have one and it works ok....

The basic premise is:

UHF ---------------(high pass filter with ---------------
cut off at 320 Mhz) |
|
----ANT
|
|
|
(low pass filter with ---------
cut off at 320Mhz)
|
|
|

| |
(highpass filter with (lowpass filter with
cutoff of 170Mhz) cutoff of 170Mhz)
| |
220 Mhz port HF->2m port

Thats about it......Not much different than a VHF/UHF diplexer but with
an extra diplexer (144/220) built in

73

Exactly.

So the problem Rich attempted to present is so outlandish that it is a moot point.
It is just another way to fuzz up the topic.

Modern PA designers are beyond using a wooden chassis, 250TH tubes, and 30 inch leads.

73 and have a good xmas.

At that speed I wouldn't consider anything but a pure digital technique. You wouldn't even need a DSP - a PIC or 68HC11 come to mind. Once you get into the digital domain you can program your filter characteristics and adjust them to fit your application.

Many, many years ago in my college rooming house a couple students felt annoyed by the loud music emanating from a nearby room. After a couple of beers they were inspired to a solution. There was an old ac-dc radio in the attic. They rewired the radio so that the 50L6 was the oscillator and lowered the frequency by paralleling the tuning capacitor sections. The oscillator used cathode feedback, since it was originally an oscillator-mixer. This meant that the plate should be bypassed. They applied raw ac to the plate and let the ac line be the bypass. This radiated enough rf into the power lines to replace the annoying music with a raw 60 Hz buzz when the device was tuned to the correct frequency. The offending radio belonged to an aspiring EE who thought for a while that the electrolytics in his radio were going out. He was, however, suspicious of the selective nature of the problem. His suspicions were confirmed by the loud laughter coming from the neigboring room. Details of his threats on the lives of the conspirators are omitted. Likewise, the names of the perpetrators have been omitted.

I am not sure if you need a narrow band device or a wideband device. An extension of this technology to solid state seems unlikely.

4253. Variable Capacitor Simulation

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-24 00:00:00 UTC
From: Macarthur Drake <m.drakejr@csuohio.edu>
Message-ID: <32BFCA22.57C@csuohio.edu>
Source record: 99349
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.homebrew,aus.electronics,rec.antiques.radio+phono,uk.telecom,sci.physics,sci.physics.electromag,sci.electronics.design,sci.electronics.components,uk.radio.amateur,rec.music.makers.bass,sci.electronics.basics,sci.electronics.misc,alt.engineering.electrical,comp.lsi,comp.lsi.cad,news.answ

I have worked on creating a varable capacitor or an element
that behaves a such. I need this element for a circuit simulation program, I
don't need such an element in real life. I need to be able to set the
capacitace to a function of time like c(t) = 2+(10*sin 6*time). The
capacitace should be able to be set to any mathmatical function and take on
any value. As you know a varable capacitor will create a current that is a
function of the capacitace, dervitive of the capacitace,
voltage and dervitive of the voltage. I have has some luck
with a collection of elements, however while the current that
these elements is correct for a variable capacitor the voltage turns out to
be scaled. I need to be able to set the initial charge on the variable
capacitor also.

Does any one have experiance in creating such an element with
pspice or any other circuit simulation program? I have been tipped to try
analog behavior modeling, but so far I have had much sucess. Any help, such
as clues or pointer to other sources or anything eles is more than welcomed.
Please resond to my email address.

differentiating the following equation:

q = c(t)*v(t)

the current from a variable capacitor would look like:

i = c(t)*v'(t)+c'(t)*v(t)

Thanks,
Macarthur Drake

Nick you can find various bits of info at the tandy support web site

http://support.tandy.com/support_electronics/15613.html

and a cell modification provided by Ross Voorhees (KB0PKT) at

http://www.zianet.com/kc5kto/mods/pro26cell.html

Hope this helps.

> >

I don't think the problem is entirely Eimac's. To the best of my knowledge, neither Dick Erhorn or Ray Heaton has ever tested a failed 8877 or YU158 for the presence of gold melt-balls.

The (Joe D. Funderburg, W6IHA) test for loose gold is simple and non destructive. The test: The anode is up, the base is down, no heater voltage present. Apply double the rated anode v between the anode and the grid. The anode is positive and grid is negative. Measure the leakage current. Reverse polarity. If the leakage current remains the same with

the anode negative, no loose gold is present. If the leakage current decreases markedly, the presence of gold melt-balls is indicated.

If anyone has a failed 8877 or YU158, or 3CX800A7 and you would like to have me test it for the presence of gold melt-balls/gold sputtering, I would be happy to test it and report the results here. If so permitted, I would like to photograph the insides of the failed 8877 or YU158 and publish the photos on the Internet for all to see. (a color photo of an 8877 that failed from gold-sputtering is shown on page 16 of the Sept. 1990 isue of QST magazine)

IMO, the thing that cost Dick Erhorn his MRI amplifier contract with GE Medical was NIH syndrome. According to a letter I received from Erhorn in 1990, he has made up his mind that ALL 8877 failures are Eimac's fault.

Dear Rich, Tom and all others who've helped me here,

You might remember me -- I'm the fellow with the TL-922 that was experiencing intermittent arcing. Rich (especially), Tom and several others tried very hard to help me out.

I'm here to report the results of my investigations. The good news is that I believe I've solved the problem -- the bad news is that I'm a little embarassed about what the cause was. More on that below...

Based on Rich's suggestions, I was on course to try one of his VHF suppressor kits in my TL-922. I am a physicist, so I was trying to understand a bit more before just installing the kit, so I fished around some more trying to figure this out.

Someone had suggested that I try and trigger the arcing by disconnecting the input from the transceiver and keying the PA while going through all bands and all combinations of tuning/load cap settings. Nothing happened. Also tried it after disconnecting the load as well. Saw no significant change in the plate or grid currents. Might have seen a barely perceptible change in the plate on 10 m, but nothing very significant. But it kept me looking...

I next tried looking for VHF resonances with 2 different dip meters - an older Heath grid-dip unit and the MFJ-259 SWR/antenna analyser with their dip coils. I found weak resonances between the plate coupling capacitor and the tubes at about 90 and 150-160 MHz. But nothing that jumped out and grabbed me. In fact, the Heath unit was quite a bit more sensitive than the MFJ (not entirely surprising) largely because of the ability to adjust the sensitivity more flexibly. The MFJ was able to see the same resonances but they were almost imperceptible - so I was unable to obtain quantitative results on the precise frequencies, depth, etc., except to say they were quite weak.

Well, I called Rich to make sure I wasn't doing something wrong. During the conversation, it dawned on me that although I'd seen the arcing phenomena on both antennas (a G5RV through a tuner, and a log periodic with or w/o a tuner), I'd never tried to see if I could make it arc when hooked up to my dummy load. Hmmmm...

To be truthful, I'd avoided the arcing at all costs - seemed like a bad idea to try and deliberately trigger an arc...I'd heard/read enough horror stories to be very cautious. When I bought the TL-922 it had some obvious arcing damage on the plate tuning cap, and I had to replace it a couple of months ago (~$130 a piece). And now the new plate cap was arcing, too, and I didn't want any more expensive parts to fail. But, fact is, I hadn't

tried it on the dummy load (oil filled MFJ model). So I did.

Well, as you might have guessed by now, I couldn't get it to arc. I tried the highest power I could muster on both CW and SSB HV settings - tried triggering it by tuning the load cap *past* the peak RF output (often triggered the arc in the past) but no arc. I was both excited and embarassed at this point. Didn't look like it was internal to the amplifier anymore. So what were the common elements between the two antennas???

I visually checked over the cables and thought of replacing them, but there was another common feature between the two antenna lines.

I have two Alpha Delta lightning/surge protectors on each antenna line (both well grounded and I thought working properly). They are the "HV" model which is reportedly good to 2KW up to 500 MHz.. When I removed them, my antennas loaded up just fine - at full power. No arcing anywhere, any band, any power.

So, I've ordered two replacement gas cartridges for the Alpha Delta's they should come in a week or so. We have a lot of lighting strikes around here and lots of static (because it is often so dry) so I really want to continue with some sort of protection.

My tentative explanation for now is that these lighting protectors were doing their job, perhaps too well. They were apparently arcing to ground when I reached some critical power level on the PA This must have been presenting the TL-922 with something like a dead short. Kinda impressive actually that the 922 has survived such repeated abuses.

That it was the Alpha Delta supressors also explains one more bit of what I was seeing - once the TL-922 arced, it was much, much easier to trigger the arc again and again at lower power. Unless I waited many minutes, it would arc at lower than normal levels - so I would wait for things to "cool off" before operating again. I had explained this to myself as some sort of thermal effect inside the 922, but now I guess that the gas cartridge in the Alpha Delta takes a few minutes for the plasma to neutralize again and go back to "normal".

I'm guessing, too, that these cartridges may have been weakened by nearby lighting strikes and reduced their ability to stand off the higher power. The Alpha Delta writeup says that they do degrade with time and should be replaced then they show a permanent short or open up completely. My condition might have been a degraded condition that caused my arcing problem. I opened up both Alpha Delta units and inspected them visually - no apparent damage other that very slight element discoloration on one of them.

In any event, sorry to be so long winded, but I wanted to present the full story to the group and be embarassed (but only a little) that I was on a bit of a wild goose chase.

I want to thank Tom R. and the others who offered their time and attention to help me solve this problem. I especially want to thank you,

Rich, for your time and delightful conversations and insights.

Best wishes and Happy Holidays to all in the group!!

Wrong again, Rich. David just informed me that the mysterious arcing was
apparently NOT due to a VHF oscillation in the TL-922.

Hi,

A while back I bought a secondhand Kenwood TR7600 with some other stuff.

First question, to UK peeps, is, the rig covers 144-148,presumably on TX as well as RX (not actually used it yet), is it legal to own ?????

And are there mods to get in between the 5KHz spacings ?? Beacause the plan is to replace my multimode with it on packet, and sell the multimode (ICOM IC260E), but our BBS is likely to be going to a 144.xx25 frequency when they implement the new spacing.

Cheers

David,

I had a TL-922 about 10 years ago. I was concerned that there was a gas discharge arc suppressor across the output, and that the manual warned about running CW with the amp in the SSB mode.

After several months of operation on 75 meters running SSB with vox, arcing started to occur. To my dismay I discovered that the band switch was arcing. The 40 meter switch connection was badly burned and unusable. On further investigation, I discovered the cause for this was that the RF input and output switching was performed by a rather large SLOW relay. At the same time, another relay was activated that enabled the bias and switched the front panel lights. The problem was that the RF relay was still experiencing contact bouncing with drive applied and bias enabled!

I solved the problem by removing the large relay, replacing it with a P&B 3PDT 110 VDC relay, with two of the poles performing the RF switching, and the third pole used to key the other relay.

The amp NEVER arced again, and the P&B relay was much quieter. I was also able to run the amp with CW in the SSB mode with no arcing.

Kenwood has made a lot of money selling replacement band switches for TL-922 amps.

Jack, WB8BFS

Hi Dave,

Thank's for the chance to touch on some more important topics. I never thought about those lightning suppressors before.

In article <01bbf1bb$53725200$976d3bc6@internet.roadrunner.com>, "David B. Holtkamp (K5KH)" <holtkamp@roadrunner.com> writes:

>You might remember me -- I'm the fellow with the TL-922 that was
>experiencing intermittent arcing. Rich (especially), Tom and several
others
>tried very hard to help me out.

<snip>

> My tentative explanation for now is that these lighting protectors were
>doing their job, perhaps too well. They were apparently arcing to ground
>when I reached some critical power level on the PA This must have been
>presenting the TL-922 with something like a dead short. Kinda impressive
>actually that the 922 has survived such repeated abuses.

Multiple things can cause this Dave. It is almost never an oscillation, it is usually an exciter spike, a load fault, or improper tuning.

The big problem is when people have this problem, they are now quick to believe it is a VHF parasitic. They stick in the suppressor kit and then later find and fix the real problem.

This all goes back to my exchange with Mario. When the PA is underloaded for the amount of drive power applied, tank voltage soars. The energy that used to go out to the load simply circulates in the system until it is absorbed as heat or causes an arc.

In your case (as in most or many), a load fault caused the tuning cap to arc. Sometimes it gets the bandswitch. An electronic grid trip circuit could help, it would likely disconnect the drive before the arc did damage. Another device that I would add is a spark gap from the tuning capacitor to ground, set to break down before expensive components.

> That it was the Alpha Delta supressors also explains one more bit of
what
>I was seeing - once the TL-922 arced, it was much, much easier to trigger
>the arc again and again at lower power. Unless I waited many minutes, it
>would arc at lower than normal levels - so I would wait for things to
"cool
>off" before operating again. I had explained this to myself as some sort
of

>thermal effect inside the 922, but now I guess that the gas cartridge in
>the Alpha Delta takes a few minutes for the plasma to neutralize again
and
>go back to "normal".

I question the use of these cartridges in a feedline anyway Dave. IMHO, they do little or nothing to protect your rig.

Look at it logically. If the device can pass a few kilowatts of RF out, it can pass more than that to the receiver when lightning strikes. Will your rig take several kW of energy on the antenna port? Mine won't take ten watts!

> I'm guessing, too, that these cartridges may have been weakened by
nearby
>lighting strikes and reduced their ability to stand off the higher power.
>The Alpha Delta writeup says that they do degrade with time and should be
>replaced then they show a permanent short or open up completely. My
>condition might have been a degraded condition that caused my arcing
>problem. I opened up both Alpha Delta units and inspected them visually
-
>no apparent damage other that very slight element discoloration on one of
>them.

I would also be concerned about the voltage from the SWR. With a 2:1 VSWR the voltage might be 1.4 times normal, that's the same as running 3 kW with a 1.5 kW PEP PA. I don't see how these things would be reliable in anything but a flat SWR system.

Just my opinion, but if it were me I'd get rid of them completely. I'd either remember to disconnect the antennas after each use, build a relay box to do it, or buy an RCS-8V that does that automatically when power is removed.

I would like to have the nichrome if you aren't using it. I'd like to measure the Q change in a PA when it is installed. I have a kit here that came in with a pair of 3CX800's (that also had an arc and the kit didn't cure it) but it may be different. On my network analyzer, that kit reduced 150 MHz Q from 3.1 to only 3.56.

Hunh? That's right, Q went UP from the stock suppressor!

Anyway, have a merry Christmas and I'm glad you found your problem. Consider eliminating those surge suppressors, I suspect they are more trouble than they are worth. And be sure to load that PA heavy enough, I also don't like Kenwoods tuning instructions. Rich and I both agree on that.

73 Tom

Surely you jest, Bobby. There's too much stuff to sort out. Even if
somebody tried to distill the discussion, that might start a fresh new
debate over the content of the distilled version.

IMO, the essence of this debate is that one side believes:

1. That virtually no VHF current flows in a VHF suppressor's inductor.
2. Nickle-chromium-iron alloys are extremely lossy at 28MHz, yet such
alloys are virtually lossless at 100MHz.

Cellular Group advertises that they can modify the Pro 26 along with
many others to receive cell freq. I don't happen to have their address
handy at the moment. They advertise in Monitoring Times all the time.
Maybe someone else has their address or it is on the Monitoring Times
web page.

4273. www.hamradio-online.com: FCC postpones RF safety rules until September 1997

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-24 00:00:00 UTC
From: vbook@vbook.com
Message-ID: <59pfir$n9f@kanga.accessone.com>
Source record: 99369

The FCC, respondig to numerous petitions filed by the ARRL and other organizations has postponed implementation of the new RF safety rules until September 1997. Under the new rules, Amateurs must certify the RF safety of their stations if they operate at 50 watts or more output power.

The complete story is available at http://www.hamradio-online.com

Jim Potter

Jim you might want to look at heating elements
the coaxial type wire inside a stainless steel jacket
simalar to the tye used in most modern oven ranges.

Cromalox and Hotwatt come to mind as a supplier of the
raw element stock and if one gets all their material and dimensional
data it might be possible to find a jacket/wire combination that will
also have close to the 250 ohm desired impedance then just immerse in
the coolant of your choice.

probably not much help

Thanks for your thoughts, Tom. How would you recommend configuring the spark gap? A sharp, point -like fixture, with minimal capacitance near the tuning cap? Might this also tend to save the bandswitch as well from damage?

> I question the use of these cartridges in a feedline anyway Dave. IMHO,

> watts!

Ummm, Tom, I think the difference is the rise time of the pulse. The fast rise time of a static discharge or a nearby lightning strike is probably much faster than the slow tuning process or voice peaks. My (limited) understanding of how these things work is that the fast rise time causes the gas in the cartridge to ionize and provide a low impedance current path to ground. They aren't really designed to handle high average power (the manufacturer recommends replacement after a big strike). It's all in the rise time, I imagine.

I do see quite a noticable reduction in antenna charging "spikes" that go "pop" in my receiver when the surge suppressor is in place. I think the static discharges (even without lightning) ain't doing the receiver front end any good. Reducing those static pops is a big plus in my mind. And besides, I hope to protect my tuner, SWR, and the 922 (?) from larger spikes and nearby lightninig strikes.

> I would also be concerned about the voltage from the SWR. With a 2:1 VSWR
> the voltage might be 1.4 times normal, that's the same as running 3 kW
> with a 1.5 kW PEP PA. I don't see how these things would be reliable in
> anything but a flat SWR system.

Good point and why I was surprised. I run generally nearly 1:1 in between the tuner and the amp. I tune the antenna on low power only, almost always presenting a nearly 1:1 to the amp.

> Just my opinion, but if it were me I'd get rid of them completely. I'd
> either remember to disconnect the antennas after each use, build a relay
> box to do it, or buy an RCS-8V that does that automatically when power is
> removed.

Ummm...As I mentioned above I think they serve a good purpose when I'm running, reducing static discharges to my receiver. But then, they don't need to be in the high power feed line to do that, now do they? I might reconfigure with the static protector just between the TS-940 and the TL-922. That does most of the good I was hoping to accomplish and removes it from the high power feed line.

> I would like to have the nichrome if you aren't using it.

I think I'm going to be keeping the kit for a while longer until I'm completely convinced my problems are solved (or until something else wierd happens! <g>).
I bet Rich might send you some nichrome if you asked real nice...or at least provide the name of the vendor he gets it from.

> Anyway, have a merry Christmas and I'm glad you found your problem.

Now that I'm not paranoid about the arcing problem, I will be following your/Rich's recommended procedure.

Thanks, too, for your help, Tom! I've learned a lot and will continue to learn more (I hope)!

Merry Christmas!

In the RAF I used a square wave oscillator connected to the central
heating system, worked a treat.

Does your Ford Ranger operate?

If so, then whats the problem? As long as it is running WITHOUT a distributor, then maybe it doesn't take in any gas. With that you would be very lucky!

4295. Heath HW101- KEYING PROBLEMS

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-25 00:00:00 UTC
From: jwg6@cornell.edu
Message-ID: <jwg6-2412962106090001@cu-dialup-0905.cit.cornell.edu>
Source record: 99295

Hi All.

I have an HW101 which is giving me some difficulty. I just recently had it overhauled, but find it is acting fishy when it comes to CW keying.

The rig does fine in "test" mode, and loads up with no problem. BUT when I switch it to CW and try to send, one of the main relays won't hold!

When I close the key, the transmitter relays kick in, receiver mutes, the sidetone comes on, and there is output. All fine. BUT if I hold the key down, for more than a second or two, the relay kicks back out, the the transmit signal is cut off. I still hear the sidetone, though.

SO if I wish to hold the key down and transmit for a few seconds, to check SWR or whatever, the transmitter will not remain ON past a second or two. I just hear the relay kick back off again. This is in the Push-To-Talk or VOX mode (doesn't seem to matter which). I have no similar problems when transmitting SSB.

If I HOLD the key down, for an extended time, the relay will keep kicking in and out and the transmit signal will go on and off at about a 1-second interval, ad infinitum.

Could someone *please* give me some suggestions on this? Why might the relay not be "holding?" I also notice that sometimes the first couple of taps on the key will not even put the rig in transmit mode immediately, so the tx won't send til I'm in the middle of the second or third letter!

The initial repairs were pretty expensive but I want to keep this rig going. (I inherited it from my wife's grandfather, W3GCN, who is now quite ill.) All other functions seem A-OK.

At this point, I can't even send my call (N1AEP), because by the time I get to the last "dah" in the "1", the transmitter relay kicks out. It is very frustrating. Any help would be greatly appreciated. 73, Joel N1AEP

Wellllll.....

In the area of motorcycles, I can tell you we have been
"Dual Plugging" Harleys for years.

The adding of the exra plug makes the fuel burn more efficiently
and can actually produce more horsepower.

Last year I purchased a Dodge Ram truck with a V-10. NO distributor,
but an interesting looking set of coils and wires going to the plugs !

Looks like technology is going EVERYWHERE, but I don't see the
alignment between automotive technology, and micropower broadcasting.

Perhaps I am just "closed minded" :)

Anyway, Happy Holidays from all of us to all of you !

4297. CB/Walkie Talkie Mods?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-25 00:00:00 UTC
From: nihilist@SoCA.com
Message-ID: <32c0a984.22629412@news.SoCA.com>
Source record: 99297

I'm curious as to whether or not a CB and/or toy walkie
talkies can be modified to use different frequencies.
For instance; I work for a place where I can get ahold of
crystals with, say, 7.91430 MHz written on them. If I was to get 2
of these and solder them into the slot originally occupied by the
walkie talkies' 49 MHz crystal, would that work?

As far as CBs go, if I bought an old CB that was crystal
controlled, then went to RadioShack and bought those ancient scanner
crystals and plugged them in, would this work for both broadcasting
and receiving?

Thanks in advance for any help.

The Nihilist

> Dave

This is still a very contentious subject!

However the bottom line is that, by definition, "BNC" is 50 ohm.
"BNC" = Bayonet "N" Connector, which is 50 ohm.

The secret is the ratio of inner conductor outside diameter to outer
conductor inside diameter (follow??!) The ratio always (should) come
out to 50 ohms. The dielectric used will alter the loss factor (Q) and
propagation velocity but will not (within reasonable limits) affect
the characteristic impedance.

The centre conductor of a 75 ohm BNC would have to be significantly
smaller diameter than the 50 ohm variety, to the point where it would
be dificult to maintain the 75 ohm dimensions at the cable
termination, be it solder or crimp. The slight advantage over the pin
engagemnent length would not be worth the trouble.

Despite the folklore folks, BNCs are still 50 ohm.

Anyone from Kings or any other connector manufacturer out there care
to get into this one?.

> amps.
>
True enough, Jack. Sagadenki, the company who manufactures the
bandswitch, made made money too. BTW, the crispy-crittered bandswitch in
"Parasitics Revisited" (Sept./Oct 1990 QST) was removed from a TL-922.
Some 922 owners have reported that other components failed during episodes
of bandswitch and/or tune capacitor arcing. For instance, the zener bias
diode shorted, and/or a current meter movement failed and/or a 1A grid
choke imploded, and/or one or both tubes suddenly developed a grid to
filament short after a 'big bang' was heard. Such damage can not be

satisfactorily explained by a simple HF switching transient. I believe its like Murphy said: "Everything is more complicated than it looks"... IMO, current transients can cause intermittent VHF parasitic oscillations.

As technology marches on, at some point you may find that your P&B 3PDT 110 VDC relay can't switch fast enough to keep up with some of the newer radios. I have heard that some radios switch in 5mS. A T/R switching circuit that switches in 2mS is shown in "The Nearly Perfect Amplifier" in the Jan. 1994 QST. This circuit is a natural for the TL-922 because it requires a +110v power supply.

The reason that Kenwood proscribes using CW on the 922's SSB (HV) tap is because the 922's HV transformer does not have enough current capacity.

: Does your Ford Ranger operate?

Yeah.

: If so, then whats the problem? As long as it is running WITHOUT a distributor, then
: maybe it doesn't take in any gas. With that you would be very lucky!

I wish I was so lucky (20 MPG).

Beats walking. I had a flat the other day. Got a drywall screw in the
tire. I wish they would come up with a self-sealing tire.

I had a Delta capacitive discharge ignition on my old van, and I
connected it to an ignition coil on the bench. I put a square wave gen
in place of the points, and cranked it up. Man, the spark jumped 3 or 4
cm from the paper clip I had in the HT lead to the case! About a
100KV. Nasty! No RFI tho, since it's CD.

You could generate RFI by taking the suppression caps out of a vacuum
cleaner motor or other small appliance. Connect some wire to it so that
it will radiate in the FM band. But be careful and don't get zapped.

Another thought comes to mind. Get a Ramsey FM-4 or other FM mono TX and
instead of operating it on 12VDC, put it on 12VAC with a rectifier in
series with the AC lead. The pulsating DC should give harmonics all over
the FM band.

What's the highest power an electron microscope can magnify? From what I understand, the object has to be plated to make it conductive, so the electrons will whatever. So you can't see things that are live like a bacterium. Am I on the right track? Maybe technology has advanced to where this isn't the case any more.

Happy holidays.

Folks -

I read where LC combonations make up resonate circuits and filters, and I see formula for their calculations. I also see RC circuits performing as filters, just as the LC circuits do.

Does anyone know the formula used to calculate the cutoff frequency of a given combination of R and C?

Thanks in advance - Mike

I don't represent Kings, but in their data book they list both "BNC" and "BNC 75 OHM." As stated in prvious posts, the 75 ohm BNC lacks the inner dielectric, and there is a different taper to the center mating pin.

Happy holidays to all,

Source record: 99313

Hi Dave and Jack,

It's interesting to read you comments Jack. poor relay sequencing has always been a big cause of tank and bandswitch arcing. I sure would love to see a TL-922 in person and find out what really needs corrected in them. I suspect some minor changes would make a large difference in reliability.

In article <01bbf1f0$5bc36e00$a66d3bc6@internet.roadrunner.com>, "David B. Holtkamp (K5KH)" <holtkamp@roadrunner.com> writes:

> Thanks for your thoughts, Tom. How would you recommend configuring the
>spark gap? A sharp, point -like fixture, with minimal capacitance near
the
>tuning cap? Might this also tend to save the bandswitch as well from
>damage?

Contrary to earlier claims that is is impossible to arc a PA from improper loadinbg or load faults, it has become obvious the real cause of arcing is operating the 922 without a proper load.

A gap would save both the bandswitch and air variable. I'd build the gap out of a very hard metal that has a high melting temperature. Stainless steel or nichrome come to mind, although there are other suitable materials. In the AL-82/1200/1500 the bracket that mounts the tank coil to the air variable is designed with an intentional overlap that puts it near the frame of the tuning capacitor. You could probably add a wide nichrome or stainless steel conductor to the stud of the air variable placing it near the frame.

Adjustment would be a matter of cut and try, starting close and backing it out until normal operation never produces an arc at that point. Of course NEVER reach inside the PA with the power on, or depend on the insulation of a tool to protect you.

> Ummm, Tom, I think the difference is the rise time of the pulse. The
fast
>rise time of a static discharge or a nearby lightning strike is probably
>much faster than the slow tuning process or voice peaks. My (limited)
>understanding of how these things work is that the fast rise time causes
>the gas in the cartridge to ionize and provide a low impedance current
path
>to ground. They aren't really designed to handle high average power (the
>manufacturer recommends replacement after a big strike). It's all in the
>rise time, I imagine.

I am not experienced enough in plasma to answer that, but since I build PA's used by people who are very experienced in plasma I can ask someone. My gut feeling is the rise time has little to do with it in this case, since lightning in a cable wouldn't have a slew rate much faster than normal RF. But that is only a guess.

> I do see quite a noticable reduction in antenna charging "spikes" that go
>"pop" in my receiver when the surge suppressor is in place.

A resistor or choke would also do that.

>I think the
>static discharges (even without lightning) ain't doing the receiver front >end any good. Reducing those static pops is a big plus in my mind. And >besides, I hope to protect my tuner, SWR, and the 922 (?) from larger >spikes and nearby lightninig strikes.

I'll hold to my postulation that if the suppressor allows a few kW out, it will let a few kW in until someone more experienced than we are changes my mind, hi. Let's both check on it independently, and compare sources here in a few days.

> Ummm...As I mentioned above I think they serve a good purpose when I'm >running, reducing static discharges to my receiver. But then, they don't >need to be in the high power feed line to do that, now do they? I might >reconfigure with the static protector just between the TS-940 and the >TL-922. That does most of the good I was hoping to accomplish and removes >it from the high power feed line.

Bingo. Not only that, but it would allow you to use one with less voltage breakdown.

> I bet Rich might send you some nichrome if you asked real nice...or at >least provide the name of the vendor he gets it from.

I'll bet you your kit against $5 he won't <grin>. No matter, I can get the size of wire from the kit in the 3CX800 PA I just got in. It's out now anyway, and the lower VHF Q stock suppressors are back in.

Message-ID: <19961225171200.MAA02810@ladder01.news.aol.com>
Source record: 99314

>The reason that Kenwood proscribes using CW on the 922's SSB (HV) tap is
>because the 922's HV transformer does not have enough current capacity.

No, the real reason the 922 is limited to one kW input on CW is it is a copy of the 220, a one KW dc input PA. The 922 even includes the error caused by installing grid chokes and bypass caps from the grids to the chassis.

Even if the transformer is made bigger, other components and cooling is marginal. The transformer problem is one of core size (KVA rating), rather than just current.

It is not relay transients that cause arcing, it is operating the PA briefly without a load when the relay switches incorrectly. This problem can be cured by something as simple as tweaking the relay contact going to the output line so it closes just before the input side of the relay. Without closing the output contact first, nearly every PA will arc something in the tank over.

4315. Disc Capacitor Markings

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-25 00:00:00 UTC
From: mhorowit@erols.com
Message-ID: <59rne1$m6d@boursy.news.erols.com>
Source record: 99315

Curious about the relationship between the markings on disc capacitors
and their values, I cruised the shelves the other day. Found the
following: '103k' on a box of .01uf, '47p' on a box marked 47pf,
'224k' on a box marked .22uf. The latter made me think the
relationship between the value and the markings was shaky.
Can anyone shed any light on what I was seeing? - Mike

4316. Home brew rotator controller?

All you need do is scale the values provided for 49-MHz up in frequency (the impedance shift at the mixer input probably isn't great enough to worry about). Same applies for the oscillator--if you are using the chip's onboard circuit. No need to over-engineer it.

Source record: 99318

Caveat Emptor!!!!!!

Got both QST CD sets for Xmas. With great anticipation, I loaded them and set out to search for an article. It took no time at all to discover the search engine / viewer associated with the package truly SUCKS! You can enter EXACT key words for the title (* wildcard is permitted) or the author or call, - or recall an (month) issue. If you remember an article, but not who wrote it or the exact title, you are SOL! ...Start loading one issue after another (10 years!) and PAGING through until you find the table of contents, then type that into the search engine.
I didn't think QST would be so crude.

I am going to call QST and complain. If enough of us do, or tell them we won't buy it until improved, maybe, just maybe, they will offer what should be a free upgraded search engine with some sophistication!

A MINIMUM improvment would be a seperate "file" containing the table of contents for all issues archived. This should then be set up so that you could page through the ToC and click on the article - then the program would ask for the appropriate CD and fetch the article. That would seem to me to be a patently obvious feature for such a large database. That is my first thought. I may have more ideas if I can bring myself to ever use the thing, as awkward as it is!

I I have missed something here let me know and I will be humbled. If not, I am disgruntled. Any comments are welcome!

>rise time, I imagine.

Right. The gas cartridge in a "1 kW rated" suppressor fires at about
350 volts. When that happens, the shunt impedance goes from many many
megohms to milliohms for the duration of the pulse. These gas cartridges
will fire within 2 nS after the voltage reaches 350 volts. Because surge
spikes up to to a very high voltage at the beginning of the pulse (as much
as a million volts in a direct strike), most of the energy gets clamped by
the gas tube (*if* the suppressor is designed properly and installed properly).

> I do see quite a noticable reduction in antenna charging "spikes" that go
>"pop" in my receiver when the surge suppressor is in place. I think the

>end any good. Reducing those static pops is a big plus in my mind. And
>besides, I hope to protect my tuner, SWR, and the 922 (?) from larger
>spikes and nearby lightninig strikes.

These static pops are typically a few thousand volts, though their energy
is minute. That's the corona breakover voltage of the antenna tip. Note
that this can be modeled as a slowly rising DC voltage charging the coax
and antenna which ultimately breaks over and discharges as corona. The gas
cartridge fires before corona potential can be reached, thus getting rid of
this nuisance. But you'll have a problem if you're transmitting at the time
because the gas cartridge will sustain conduction once it fires until current
drops to zero for a microsecond or two. You need a different static drain
arrangement if you'll be transmitting in conditions where corona can occur.
A high value choke shunted to Earth works dandy for draining static.

>> I would also be concerned about the voltage from the SWR. With a 2:1 VSWR

>
> Good point and why I was surprised. I run generally nearly 1:1 in between
>the tuner and the amp. I tune the antenna on low power only, almost always
>presenting a nearly 1:1 to the amp.

Yeah, high VSWR will cause them to fire. A 2:1 VSWR can have up to 384
volts on the line at the voltage node, and that exceeds threshold. Of
course voltage will be low at the current node. Placement is important
in cases like this. Running a flat system is best, but you can make
sure the suppressor is at a current node for a single band installation.

>> Just my opinion, but if it were me I'd get rid of them completely. I'd

>reconfigure with the static protector just between the TS-940 and the
>TL-922. That does most of the good I was hoping to accomplish and removes
>it from the high power feed line.

Bad idea. The suppressor should be the outer perimeter of your station
defense. It should be mounted in the entrance bulkhead serving as your
station ground window. When it fires, it will attempt to shunt all the
surge current to Earth, and that can reach 8,000 amps in a strike. You
really don't want the tuner and the amp in the way of that surge.

Note, the instantaneous power in a strike is on the order of 3 *billion*
watts, but of course the duration is short, only a microsecond or two,
thus the energy is low enough for the gas cartridge to sustain for the
brief moment needed.

Alpha Delta and Lynics suppressors have a design flaw which can render
them useless in some situations. This flaw is that they have DC continuity
on the inner conductor. If they are driving a low impedance, like a cavity
loop, a huge current pulse can pass through the loop before voltage rises
enough to fire the gas cartridge. That current pulse will ring the cavity
and still hit your equipment with extreme voltages. Polyphaser uses a
much superior design which has a series capacitor in the inner conductor
path. While the surge is charging that capacitor, voltage rises enough
to fire the gas tube (located on the antenna side of the cap), and
prevents the sort of problem the AD and Lynics suppressors have with
DC shunts in the load. If you don't provide a DC shunted load, however,
the AD and Lynics suppressors work fine.

Or, go to your local motorcycle shop and buy some stuff called "Slime".
Put this in your tires and never get a flat again! (unless you really
put a big hole in the tire!

However, warn the guy at the tire shop before he dismounts a
Slime-trated tire, as the stuff isn't called "Slime" without good
reason!

Meanwhile back at r.r.a.h....

Hmmm, ok, in computer connections, we used RG-62, which I believe is 92 ohm cable.
The BNCs that we used were specifically designed for the cable (it's noticably
smaller diameter than RG-58 or RG-59.)

They were Amphenol connectors, although I don't have the part number here.

Anybody care to speculate if those connectors were really 50 ohm? Seems like
a significant mismatch would occur.

Yes it's true. The cable has a small pcb enclosed in the 25pin D
connector, mounting a simple limiter amp. e.g. 741. This is powered from
spare lines on the COM port.

The software - HamCom - drives the lines high + and low - for the rail
supplies and it polls a line from the amp. output at high speed. It senses
data present and calculates validity and data value from the results. This
can be code, rtty, hffax, etc.

Look at Maxim product data. They do both continuous-time (linear) and
switched-capacitor filters, both of which can be made
electronically-tunable, and you can get up to at least 8th-order responses
from a single chip. I have no connection with Maxim except as a satisifed
user. Maxim also treat small users better than many semiconductor
manufaturers do.

>following: '103k' on a box of .01uf, '47p' on a box marked 47pf,
>'224k' on a box marked .22uf.

There are several different systems in common use.

47p is obvious.

"103k" and "224k" are less easy to read. First of all, discard the "k" - it refers to the dielectric material and has nothing to do with the capacitance. That leaves you with three digits to interpret.

In the three-digit system, the capacitance is in picofarads. The first two digits are significant, and the third is the number of zeros following the first two. So "103" is 10 followed by three zeros, ie 10000pF which is indeed 0.01uF. Likewise "224" is 22 followed by four zeros, ie 220000pF which is 0.22uF. This system is also universally used for chip resistors, so "103" would be 10kohms and 224 would be 220k.

The one you have to watch for is "220" etc, because the final 0 means "no zeros". In other words "220" would mean 22 ohms or 22pF under this marking system. But under a third system, "220" could mean simply "two hundred and twenty", so sometimes the only solution is to measure the component.

Yet another system would mark these same capacitors as "10n" and "22n", where "n" stands for "nanofarad" (1000pf). To avoid confusion due to the decimal point being illegible, the "n" is sometimes used instead, so "4n7" would mean 4.7nF, and "6p8" would mean 6.8pF. The same applies to resistors, so that "4k7" would be 4.7k and "2M2" would be 2.2 Mohm.

A very useful clue to identify the marking system is to check for preferred and non-preferred values. For example, "224" would never mean 224pF because 224 isn't a standard capacitor value. It has to be some multiple of the industry-standard preferred value 22.

How about an MF-10? They're cheap, and easy to find. You tune them with a clock that's 100x Fc. You can get a 4th order BPF with one chip (both sections 2nd order X2). Meets all your requirements. Sounds interesting, tell me more about your project. I have used the filters extensively. Nice, cheap, easy.

The value appeared in a feedback about 2 or 3 issues after the original
article. The problem I see with the design is the relatively shallow
notch- about 20 to 30 dB as I recall. Our filters achieve a notch depth
of over 50 dB with an in-band insertion loss of 0.5 dB worst case. In
addition, ours are transparent at 70 cM for dual band rigs w/ a single
RF port.

It's a positive spike - check it with a 'scope. And the diode will slow
down the
release of the relay because it keeps current flowing longer in the coil.
If you
use a MOSFET usually you can forget the diode because many 'Fets are rated
for breakdown operation.

But your main point is entirely correct.

We simply used a signal gen and little RF amp. Makes a nice silence on
an FM radio. For AM and records (this was before CD's) we used Motorola
4 Watt UHF portables placed against the common wall right behind the
stereo. Kinda makes the speaker cones want to pop out, ya know?

The silencing acquired a term with us... we called it "Waveteking," as in:
"We had to Wavetek the neighbors three times today!"

Take a relay. Wire it as a buzzer. Feed raw AC to it.
Instant SPARK Gap! I fed 18 volts from a toy train transformer to one
in my teens (back in the early 70's). Connected to a 100 ft longwire
antenna it radiated for 6 blocks...

There is a mod for the Pro-26, but you will have to order some parts
for it. You can either order just the UK CPU which takes a
considerable amount of skill, or you can get the logic board with the
CPU already attached. The latter doesnt even require soldering skills,
mainly screwdriver skills. Look at http://www.demon.co.uk/javiation/
for more information under the the Pro-26 subpage. This mod would make
the Pro-26 an awesome handheld. I wish that I had a few extra $$ to
spend.

Richard,
Check this page:

http://www.concentric.net/~n9zle/hc.html

Bruce, N9ZLE sells the hardware interface you need, and will give you the HamComm/JVFax shareware you need to make it work. It plugs into a serial port on your computer, copies CW, RTTY, PACKET (crude form), SSTV, and WEFAX pictures. It costs a whopping $20 usually, but they are on sale for $15 for Christmas. Once you get the software, there are schematics in the DOC files to show you how to build other interfaces if you are interested. I bought one a few months ago, and use if for HF WEFAX pictures, and it works great. Be aware that there isn't any hardware that copies 'perfect' CW. How well any of the hardware devises copy is very dependent on the strength of the received signal and the way the CW is being sent.

>ohms are violet, 78 ohms blue, and 50 ohms green. The 75s looked like
>the 50s except for the dialectric as mentioned in the original post.
>The 78 onm cable was twinax.

There are 75 ohm BNC's and N's, and 50 ohm BNC and N's.

I have both types downstairs. The 75 ohm N's have a smaller pin, screwing
a 50 ohm male into the female 75 ohms N will ruin it.

The 75 BNC's use the same center conductor, but have mostly air dielectric
inside instead of a sold PTFE or poly insulation.

My Suhner Connector catalog lists 50 ohm and 75 ohm connectors (under
different part numbers) for BNC, TNC, and N types.

Suhner includes a warning on N types that 75 ohm and 50 ohm connectors can
not be mated because of center pin size differences, but they also
indicate it is NOT a problem with BNC's and TNC's because only the
dielectric is different!

So there really are 50 or 75 ohms BNC, TNC and N connectors. But there are
no 50 ohm UHF type connectors,, hi.

> Such damage can not be
>satisfactorily explained by a simple HF switching transient. I believe
>its like Murphy said: "Everything is more complicated than it looks"...
>IMO, current transients can cause intermittent VHF parasitic
>oscillations.

In the past you claimed there was only ONE cause of PA problems for
everything from boiling gold to melting glass, and acing tubes to sparking
capacitors, PARASITICS. Even though we now suddenly hear a Murphy quote
saying everything is more complicated than it looks, the answer is
still.....PARASITICS.

The new claim is: The HF risetime of 1/2 uS or faster is too slow to
induce parasitics, but relay switching or bias rise time is not.

Look at what happens when the relay is closed. The cathode bypass and
coupling capacitors are all charged to cut off bias, and the dc common
mode current in the filament choke is near zero.

When the relay closes, the bypass capacitors must discharge through the
relay contacts and meter shunts to ground. The coupling capacitors must
discharge through the dominant common mode impedance of the filament
choke. We know the current rise time of the choke is much slower than the
HF operating frequency, or the choke wouldn't be a good choke. Rise time
from relay closure has to be much slower than the operating frequencies
rise time, or none of these bypass and coupling components would be
effective.

Closing the relay too late or too slow ONLY causes a problem if the PA is
operated without a load (even for a few RF cycles). If Jack would have
just tweeked the contacts slightly, making the output RF contact close
before the input RF contact, the problem also would have gone away.

As with the problem Dave had (caused by the lightning suppressor arcing)
Jack ran the PA without a load for a second. In both cases it allowed the
tank circuit to build up HF energy until something arced.

The parasitic induced tank arcing claim, like so many others, is
incorrect.

>quad antennas built them because his yagis kept dissolving in teh chronic >corona discharges at high altitudes in Peru. Don't remember all the >details, but was interesting.

I have corona problems here Dave, at a few hundred feet above sea level. In Death Valley, they even occur below sea level. We are talking receive, not transmit.

The problem is the accumulation of charges during proper weather conditions. There are a great many causes. Dust storms, snow storms, rian storms (even on the horizon) or even wind can cause this effect.

I disagree with the theory that ionization of the discharge tube would help your receive problems. While I do not know a lot about the mechanics of the dischrage tube, I have considerable experience with receiving systems and noise elimination.

There are two sources of noise invoved in this, one is the sizzle or whine of the actual corona discharge, the other is the pop of an small arc in the system. Grounding the antenna, using a bleeder resistor, or any for of discharge tube will NOT affect the sizzle or whining noise from corona. Only a change in voltage gradient or RF impednce of the antenna near the point of discharge will affect this type of noise.

A quad is quieter than a vertical for one reason, the quad antenna has a less abrupt point at the highest end and the sharpest ends (corners) are usually not at the high impedance area of the antenna. The high impedance noise source has to directly couple noise energy into the antenna at a lower impedance point. The antenna also has a large area spread out over the highest point in the system, minimizing discharge.

Since current is very low in the discharge (but the voltage very high), the discharge off the high end impedance of the vertical couples noise energy into the antenna more effectively. Plus the tendency for corona is generally greater in the vertical, because a single point sticks up and concentrates the electric field.

The smoother, rounder, and larger the area of the antenna, the less corona.

So much for the sizzle.

The pop is caused when something (for example the feed cable) charges up. Eventually the voltage breakdown of a coupling capacitor (such as the variable capacitors in a T network tuner) or air gap (as found in a switch or connector) breaks down. That's the loud pop.

You will hear this pop with a gas discharge tube, or a spark gap. The only cure for this pop is a leakage path across "the thing" charging up. Either a high value resistor or a choke works equally well, since the charging current is very very low.

DC grounded elements eliminate the "pop" caused by the sudden arc discharge described above, but can NOT reduce or eliminate corna noises at the operating frequency. A 100k resistor across the feedline would do as much as a choke, and both would be much more effective than the gas discharge tube at reducng that effect.

Personally, I think the discharge tube is a waste of time unless you want additional but marginal protection for close-by strikes. The only sure protection is to totally disconnect the feedlines and AC connections from the rig by unplugging them.

The goal is to save money on repairs, and that transmission surge suppressor has already cost money and time. A $10 relay and ten cent resistor would do much more, unless you plan on operating during lightning storms.

I'll leave the utter irony of this statement as an exercise for the reader.

> Sagan was more of a showman than a scientist.

Carl Sagan was the chairman of the Astronomy department at Cornell University. Furthermore, he was a scientific consultant to NASA on many projects. Sounds like a scientist to me. Unfortunately, most scientists do not have a talent for making scientific ideas known to the layman. Carl Sagan did have that talent. All of his books (even the fiction) conveyed scientific knowledge to the layman in a way that was lucid and understandable. And, yes, he was a showman. His presence in the Cosmos series was what made the series so compelling.

> He promoted as facts things, that at best, were conjecture.

This is another pitiful jab. I suggest, Mr. Cagle, that you actually READ some of Sagan's material. When you do, you will see that Dr. Sagan NEVER stated ANYTIHNG as fact that was not widely known to be fact. Anything that was speculative was clearly stated as such.

>faster not slower! Where have I gone wrong?

You haven't. The fastest passive way to rid inductors of current is to decide how much back bias you are willing to tolerate, and then put a ZENER DIODE of this rating across the coil in series with a regular diode going the other way (to prevent conduction when the coil is energized).

A regular diode only drops 0.6 volts, so that voltage times the coil's diminishing current is the power dissipated in the diode - equal to the rate of energy loss stored in the coil's magnetic field. If you could tolerate 60 volts, then the power (same current x 60 volts instead of 0.6 volts) would be 100 times more, and the magnetic energy in the coil would be sapped 100 times more rapidly.

ANS: Yes, they can but you are limited by law and type acceptance
practices from doing this. There are some instances wherein they
may legally be converted to the Amateur Service. As you didn't list
a call sign of any sort, it is difficult to advise more specifically.

>QUEST: For instance; I work for a place where I can get ahold of
> crystals with, say, 7.91430 MHz written on them. If I was to get 2
> of these and solder them into the slot originally occupied by the
> walkie talkies' 49 MHz crystal, would that work?

ANS: I doubt if this will work. It would depend on the type of crystal
being used in the transmit and receive portions of the Walkie-Talkie.
Your hypothetical 7.91430 MHz crystal is probably a fundemental freq
type.
Most of the cheap W/Ts use multiple 3rd or 5th overtone crystals
operating
on the desired frequency. Some of the more expensive types may use low
freq crystals, but have more complex hetrodyning circuitry.
>
> QUEST: As far as CBs go, if I bought an old CB that was crystal
> controlled, then went to RadioShack and bought those ancient scanner
> crystals and plugged them in, would this work for both broadcasting
> and receiving?

ANS: You might luck out and it would work, but it is very doubtful
that the scanner xtals would get you any place close to where you want
to
be. Also, as this would obviously not be converting into the licensed
amateur service range, it would be illegal and would not comply with
normal type acceptance guidelines.

Source record: 99259

Does anyone have the old QST (from the early '60's) that describes this novel form of communication? A few points I remember---required low power, about 50W to reliably communicate several thousand miles, free from qrm,etc. Involved unique antenna systems by which you could "tune" to a specific magnetic line of force (earth's magnetic field), modulate it, and use as a medium for communication. I have never seen m.e.m.f.t.a.c. (modulation of earth's magnetic field to affect communication) mentioned again.

Any info is welcome.

Thanks very much, es bcnu!

Source record: 99260

I also got both CD sets, and have a few comments. First off, what you get:

1) A rather simple search engine (as has already been noted).
2) Individual scanned (black and white) images of each page of an issue. (This includes the front cover, but I'm not sure about the back cover.)
3) "Database" containing the article name, column name, author's name and call, issue, and page number.

Given the pages were scanned and not OCRed, there isn't much you can do for searching the actual issue text. However, I did find the data file used to build the database on the first CD of both sets. This contains all the index information in a raw text format.

Without too much work, it would be possible to build a better search engine. It would be nice if the ARRL was able to do/offer this, but time will tell. Certainly, it would be possible to move the raw data files to a system with better tools.

One thing I also noted: the search engine doesn't use standard Microsoft data entry accelerators. In other words, TAB doesn't get you to the next field, but ENTER does; HOME and END don't work in the text entry fields, but the arrow keys do. Sigh...

Having worked in the software field for the past 20+ years, I'd say there is room for improvement (a understatement :-)

HOWEVER, if you look at the CD sets as a way to acquire the information with about the same search capabilities as a paper index (such as you might find published in the January issues of many magazines), you'd be just about on target. (My main gripe here is the search results don't include the issue, so you can spend a lot of time swapping CDs. I've already let the ARRL know about this.)

I'm happy with my purchase, and I'll be purchasing the remaining CDs whe they come out. I'd expect the ARRL to offer improvements as more and more people use the software and offer suggestions.

Shane, CTCSS tones are usually numbered/identified with a LL (letter
letter) or LN (letter number) type scheme.

Ie: 100.0Hz = 1Z
123.0Hz = 3Z
241.8Hz = M6

There are about 42 odd standardized CTCSS tone frequencies. Many CTCSS
encoder/decoder circuits can not deal with more than 32 different tones
- simply because they don't have enough divider/address lines/aka DIP
switches. If your radio is using the above numbers for CTCSS tone
frequencies they could be totally different on another radio. To
confuse the matter some more, there are several non-standard CTCSS tone
frequencies in use too. I find it best to use the full frequency in Hz
just to avoid any possible confusion. Hopefully your encoder/decoder
with be compatible.

Rebuilding a old homebrew amp. I would be interested in purchasing power supply components like;

Plate transformer w/240vac pri - rated from 3KVA up, goal of 5-6KV DC, will use doubler or bridge, so...
Ideally, a hypersil, but, what you got?
Oil filter cap(s) rated for the above, and providing a total of 80+ MFD. Going in a rack, so needn't be small.

Once I get this completed, I'll be adding/upgrading the decks, so let me know if you have Heavy Duty amp items.

Happy frying!

A while back (maybe 6 months) somebody posted a message about converting RS walkie talkies to 6M. Supposedly, they had a crystal for transmit and receive, and all you had to do was change the crystals, because the frequencie difference was so little. Has anyone had any experience with this or converting any other walie talkies? Thanks,
Andy, KB0MMU

Will so many remember you at your death?

> Sagan was more of a
> showman than a scientist.

A corpus of over 200 scientific papers written by Sagan soundly refutes
your vaccous claim.

> He promoted as facts things, that at best, were conjecture.
^^^
Gentle readers of this, please make a note of this comment.

Exactly WHAT are you refering to? Please, exactly which conjectures did
Carl promote? Be specific.

> He could not believe in God so he looked for aliens.

In my mind, aliens are more likely that a god or gods. And Carl
frequently made note that it was entirely possible that we are alone
in the cosmos.

BTW: Doesn't a god fit into your category of "conjecture"?

> He thought life should be ubiquitous in the universe but did not >understand that the
universe itself is alive.

Your statement makes it implied that YOU think that the universe is
alive.

Support your claim, or admit it is not fact, but is pure conjecture
on your part.

It seems to me that you are doing exactly what you claim Sagan did.
And further, I'll bet you don't have 200+ scientific papers to your
name.

4362. Need help for SERVO CONTROL

I am hopeing a fellow HAM would be able to give me some advice on the design of a low cost, CLOSED LOOP SERVO CONTROLLER that would support ttl signals that provide for motor pulse(step) and direction. All the info that I have come across so far deals with motion control chips like the LM628/629. These chips are very expensive and require a host processor. This application is for antenna control. The servo,s that I have provide the incremental encoder output pulses. Any help on this project would be greatly appreciated.

Thanks, Steve Carlisle VE7AHL

Helmet-mounted military-surplus 50 MHz tranceivers can be purchased for
about $50 each, and already cover most of the 6M ham band. All you have
to do is get a 3.2V battery/supply. Unlike RS HT's, these won't break
when you shoot them, either.

All you have to do with the RS units is replace the crystals. The TX
crystal is at the operating frequency (3rd or 5th overtone) the RX
crystal is the receive freq. - the 10.7MHz IF. All I did was blow up
the tiny schematic in the back of the manual on a copy machine and
send it to Cal Crystal with a note saying "Make me TX and RX crystals
for 52.525MHz that will work in this radio." and they took it from
there. International Crystals can also do this.

You can adjust the input antenna matching coil and TX PA coil for
slight improvements, but in general, they don't need to be
modified any further. I also looked up the RX IC and found out
where to put a squelch control and added one.

I'd like to hear more about the military headsets. Where does one
get them for $50?

What band range is the GE MSTR II???If the combination number doesnt end with a 33 (IE: MC74KAN33) but a 23 or 13, you are out of luck...a 33 is the 42-50Mhz version...the 13 is good to go to 10mtrs (25-36 Mhz)...the 23 series is good for nothing except parts (36-42 Mhz!)

To move a MSTR II 33 series to 6mtrs, order new xtals from any good manfacturer like ICM (say for 52.525 Mhz simplex), solder the xtals in CAREFULLY into the ICOMs, and then retune! make sure the radio WORKS on the current channel first before attempting to retune...
You will need a signal generator (for the rcvr), a voltmeter or GE test set to tune the LO and exciter, and a wattmeter to set the output!

Date: 1996-12-26 00:00:00 UTC
From: David Whipple <david.whipple@m.cc.utah.edu>
Message-ID: <32C32F36.1B70@m.cc.utah.edu>
Source record: 99272

I'm pretty new and electronic-illeterate. Is there anything wrong with using a wooden frame and wires to create a cheap, makeshift yagi? I know you can make quat antennas with the same materials, but I'd be interesting in any way of making a _cheap_ 2 meter yagi without needing too much expertize. I've made a simple groundplane with a chasis mount and a couple of wire coathangers, and I'd like a yagi equally as cheap.

Any input would be great.

Thanks

David

A couple of years back QST had an article called "7dB for 7 bucks" that outlined how to make a cheap 2m yagi from PVC pipe and brazing rod. The antenna worked great and we still have several folks in our club using them for T-hunting. Check the article out!

Well, Fred, I'm not sure I can explain it to your satisfaction, but here
goes:

We have a lot of dust, wind, and other charge-buildup sources around here
(quite dry most of the year at 7000+ ft in northern NM). I know from
experience that with the same antennas that I described earlier (G5RV and
LPA), the static buildup (particularly when the wind was blowing) would
cause loud "pops" to be heard in my HF receiver more on the lower bands but
would be audible (but less strong) up to 10 m. These pops I guess were the
static discharge through the front end of my receiver, an event that
undoubtedly does not do it any good.

In fact, the static buildup is sometimes strong enough (in clear weather
and absolutely no lightning for hundreds of miles) that placing the
unterminated antenna connector near a good ground will demonstrate
significant sparks that are visible to the eye in a darkened room. One got
me while I was holding the connector once and grounded from my hand through
my knee into the grounded metal desk through my clothing. I was shocked --
pardon the pun -- but convinced of the reality of this charging. Other
times of the year it is not nearly so intense (light right now) but in the
Spring particularly, it is bad.

I've also had an alarming experience when holding my LPA antenna lead
when lightning did strike a few miles away. It was a sizable strong shock
that didn't quite throw me but definitely caought my attention. I'm
guessing the distance to the lightning strike because I didn't see the
flash directly, but heard the thunder some seconds later. Subsequently I
was much, much more careful when holding antennas when lightning was
nearby. Calculations for a several mile distant source at instantaneous
field strengths of many kv/m divided by r**2 and then multiplied by the
length of my antenna resulted in voltages in the hundreds of volts range.
Not to be ignored.

As for the static pops, its a lot harder to do some sort of quantitative
analysis there, but I know from experience that I still hear the pops on
the receiver under similar static charging conditions, but the amplitude is

much reduced. Hence my conclusion that the Alpha Deltas were doing me some good in that area.

Hope all this is helpful!

> since lightning in a cable wouldn't have a slew rate much faster than
> normal RF. But that is only a guess.

Fair enough. I'm a nuclear physicist and never did like plasma physics
much anyway <hi>. I think the rise time is critical for initiating a
breakdown of the gas. Remember how the old fluorescent lights used to work?
Seems like I remember that they had a HV pulse to get the discharge going,
but once triggered, it is easy to maintain. I think if one went to a much
slower rising pulse, the required voltages/powers are higher.

As for comparisons with RF, the frequency of the RF is not really
relevant as much as the rise time of the power pulse. I think they are
significantly different from a lightning strike.

But let's ask around. I'd be delighted to be corrected on this one
(too!).

>
> Bingo. Not only that, but it would allow you to use one with less voltage
> breakdown.

Yep! This is the better place to put one of these, no doubt.

> is minute. That's the corona breakover voltage of the antenna tip.

Consistent corona discharge probably would occur only at higher altitudes
than mine (I'm at 7000 or so - I'd expect chronic corona problems at
10000). In fact, I think one fellow who had a lot to do with the design of
quad antennas built them because his yagis kept dissolving in teh chronic
corona discharges at high altitudes in Peru. Don't remember all the
details, but was interesting.

> Bad idea. The suppressor should be the outer perimeter of your station

>the characteristic impedance.
>
It depends what you define as "reasonable limits". In a solid dielectric transmission line, the impedance is inversely proportional to the square root of the dielectric constant. A coaxial connector is a short section of transmission line, partly air and partly solid dielectric. So the dielectric does matter - but in practice it's always PTFE in Ns and BNCs.

>The centre conductor of a 75 ohm BNC would have to be significantly

>be dificult to maintain the 75 ohm dimensions at the cable
>termination, be it solder or crimp. The slight advantage over the pin
>engagemnent length would not be worth the trouble.
>
All that is based on the incorrect notion that 75 ohm BNC's don't exist.
In reality they use a combination of reduced inner-conductor diameters
and air gaps to raise the impedance.

>Despite the folklore folks, BNCs are still 50 ohm.
>
Sorry, that just ain't true. Both impedances are freely available.

>Anyone from Kings or any other connector manufacturer out there care
>to get into this one?.

No need - just read the catalogs.

>73's Bob VK1ZRE

>---
We used 75ohm connectors and cable on some level/interface converters
we built a few years ago. Trompeter was source. The patch cords for 75
ohms are violet, 78 ohms blue, and 50 ohms green. The 75s looked like
the 50s except for the dialectric as mentioned in the original post.
The 78 onm cable was twinax.

FOR SALE:
Double-Pole - Double-Throw Knife Switches
these are great for use in 450 or 300 ohm
ladder line antenna systems, to switch
between two antennas or from one antenna to
two different tuners, etc... they are made
in USA by Leviton, plastic base, all brass
metal parts, 1.25" x 2.25" in size, 6/32 brass
screws for connections. I have seen similar
ones at radio shack (for switching tv lead-in),
but these Levitons are a LOT more heavy duty.
I have used them at KW levels with no problems.
I have about 50 of them left...
I'll mail you 3 switchs for $10. postpaid (USA).

I think you meant fully _limited_ signal.

Well, the original post (cut out here) said that it only had to work a
few dozen feet. At that distance, any RFI generator could overpower a
strong station and cause interference. And then there is the possibility
of getting right into the IFs at 10.7 MHz, for some more interference.

Like with murphy's law, doo-doo happens. Try it before saying it won't work.

Hi again! NEED MORE OLD SB-xxx BOXES!! (smaller ones):

I'm the guy hunting old SB-xxx boxes. You've probably seen my
posts lately. I am building a completely homebrew vintage station using
old SB boxes for the chassis, and completely reworking them. It's
coming along well so far. I've been trading around the groups
to acquire all of the luscious parts of the last 40 years that they
just don't make anymore.

I now have 2 SB-101/2 boxes, and now I'm turning my attention to the
speaker, and the station console which will contain a vintage design
tube speed keyer, 24 hour mechanical (!) clock, and tube TR switch.

Here's what I need to buy:

I need to find ANY old SB-610, SB-614, SB-xxx, SB-xxx-matching-speaker box,
SB-430, or ANY other of the smaller SB-series boxes that have the same
box style, but are smaller. GUTS ARE NOT NECESSARY, but won't go to
waste if included. I save EVERYTHING to homebrew with. Price range
of $10 to $25 is about as high as I can go. Other than the case, faceplate,
and chassis being undented, looks are absolutely unimportant, and if
ugly = cheap, then sell me ugly!

The station lineup will be a 3 tube (actually 6 sections, so in the old
days would have been 6 tube!) super-het for 80m with a converter for
160, 40 & up. The transmitter is all band 160-10 (no warc) 50 watts CW only
with a built-in VFO. When I find a third SB-102 or SB-101 box, that
will be for an 811 (250 watt) amplifier to match the series.

I'm painting all the boxes Collins-esque two tone grey. All of the dials are
old National or clones of that, including SCN verniers.

So dig in those garages and see what old dead SB stuff is there. I have
been paying around $20 for a SB-102 case, less parts (one had parts and
the fellow generously left 'em in - not a speck to be wasted!). Again, I
don't need ANY working units or any boxes with values much higher than
$10-$25. I just can't afford them.

email inquiries to:

Dave gekko95@ix.netcom.com

Tacoma, WA

Thanks alot in advance, and Happy Holidays to all.

I'm not sure if this is the same thing, but I remember having
read that Tesla calculated the earth's resonant frequency (Was
it 7.69 Hz?) and he somehow got the notion that if you excited
the electromagnetic spectrum at this rate, you'd be able to
communicate world wide.

Unfortunately, building a transmitter and a receiver for
this frequency isn't a small affair. Further, the
communications bandwidth isn't very good. You weren't reading
one of those famous april fools articles, were you?

From: "Brian K. Short" <ke7gh@primenet.com>
Message-ID: <32C40FE3.4F95@primenet.com>
Source record: 99196

Please excuse the negative tone of this information, but I am just forwarding it and folks do seem quite interested.

I do not know of a "replacement" journal." QST Jan 1997 had a nice review of the SCS PTC-II Pactor II controller. They have had several advanced digital articles lately. I have not seen nearly the coverage of Clover ANYWHERE else...

I personally will miss the "RTTY Journal." I received it back in the 80's and while not a glitzy, glossy publication at that time, I enjoyed reading it. As you know, the "RTTY Journal" has been around for quite a number of years (I've only been a ham since 1974 myself).

Many have commented about the economic realities of amateur radio organizations (shrinking numbers, reluctant sponsors), but also there has been a large trend to distribute information (more quickly and also more efficiently) via internet. Internet provides EVERYONE with access to "publish." There really are no editors/censors etc on internet (for good or bad).

Personally, if anyone has information of publication quality (or otherwise),
I would be happy to include it in my web page(s) or include a link.

73, Brian http://www.primenet.com/~ke7gh/

All I know is that I --and presumably everyone else-- received a plaintive plea for support from IDRA/DJ earlier this month, with the declaration that the mag was gg bimonthly. I responded with a show of faith-- a check for $32.

So, on the one hand, we have a statement about reorganization and staff changes and a plea for support, answered in my case. On the other hand, we have a flat statement from the departing Editor that the show is over.

Which is it, please?
--
Garry Shapiro, NI6T
Editor, The DXer

I don't want to seem like a Monday morning quarterback, but...

I seem to recall in a recent DJ, there were comments about paying off debt ahead of schedule (correct me if I'm wrong).

I'm no economist, but I do run small business. The way I see it, one
should not retire debt early, unless there is an ABUNDANCE of cash
flow. If anything, debt should be refinanced to extend the term and
decrease each payment, to try to salvage the company during a cash
flow crunch.
Can anyone explain?

Message-ID: <Faz8vBA6kDxyEwIx@ifwtech.demon.co.uk>
Source record: 99198

Thanks to L.Mark Pilant for a very useful review.

It seems that the search engine is exactly the same as for the 1995 CD-ROM which was published last April - with all its strengths and weaknesses.

A year's issues appear first as a vertical list on the left-hand part of the screen, rather like a directory list in Windows File Manager. You can then expand each issue into a number of general areas, and then each area into individual articles etc - all the way down to the small-ads if you want. The selected text appears on the right-hand part of the screen.

When you enter a word or phrase to search for, the number of "hits" appears next to each month's issue in the vertical list, and in the right-hand text window is the text begining at your first "hit", which is highlighted. You can very easily jump along from one highlight to the next.

It should now be clear to the sender of an earlier message that the whole text is indexed and fully searchable, and is not simply scanned-in pages. Only the diagrams are scanned-in, and are accessible by clicking on the references in the text. If you choose to print a selected article, all the diagrams and photographs are automatically included, each on its own page.

What disappointed me about the 1995 CD-ROM was that it makes no use of the Classified Index which appears in the December issue. It's there, of course, but all the index entries are "dead" - you can look but you can't click to jump directly to an identified article. Worse still, the Index only gives month and page numbers, and there's no way to jump directly to a page number. (Mark: is this the same in the new QST sets?)

I agree with Mark about the dialog boxes and other features that are not fully Windows compliant, and therefore more difficult to use, but presumably these "misfeatures" are built into the search engine that ARRL bought as a package. The other annoyance is that the Help system doesn't work like normal Windows Help - it uses the search engine itself. Now if you're having trouble using the search engine... see what I mean?

Mark said:
>If I had it to do all over, would I purchase these CD sets? Without >question: Yes. Will I be buying future sets? Yes.

Based on experience with the 1995 QST CD-ROM (which also includes QEX and NCJ), and Mark's review, I will be buying the CD sets.

>Are these for everyone? No.

Not if you already have the relevant QSTs and the space to store them.
For everyone else they're well worth considering.

One final thought: when reading articles on-screen, and viewing each diagram in its own separate window, I found something getting in the way of my understanding. It was easier when the articles were printed out, becasue then I could flick from page to page and leave bookmarks (fingers) at the most interesting parts. But printed output from the CD-ROM is done in word-processor style with long lines across the whole page, and illustrations on separate pages. That still isn't as easy to understand as the original QST pages, printed in columns for ease of reading, and with the relevant illustrations on the same page wherever possible. It showed very clearly how much the page layout contributes to ease of understanding - we'll miss it in a few years, when it's gone.

I'm fairly new to working with vacuum tube radios. Recently, I bought box of tubes to use and there were about 60-70 tiny little tubes -- about 5/16 - 3/8" in diameter and about 1 - 1 1/4" long. Some had regular pins coming off of the bottom, but most have insulated wire, about an inclh long. Some of the numbers are: JG-6021, JG-6111, AF-5840, JG-5896, 5641, JHS-5977, AF-5636, ...

Are these "pencil tubes"? What were these little guys used for? Portable electronics? Do they have any practical use now?

Thanks and happy new year!
Steve

4393. IVEX WinBoard PCB layout - using it? panelizing boards?

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-27 00:00:00 UTC
From: Dave Curtis <ng0x@ricochet.net>
Message-ID: <32C47FA7.49BA@ricochet.net>
Source record: 99204

For about a week I've been doing some PCB layout experiments
using WinBoard from IVEX. (See below for "what is...?")
Anyone else using it? Has anyone had boards fabbed from
its output? I'm still at the stage of doing small layouts
and learning my way around. So far, I've done 5 small
two-layer boards that include copper pours, and also I've
started my own component library and added a few things for
odd-ball footprints.

Now my problem: I'm trying to make a panel out of the small
boards so that I only pay for plotting and set-up once for
these boards. But those darn copper pours don't drag, and they
don't cut and paste. And if I re-enter them, they don't
connect up to the pads that they used to. Anyone solved
this problem?? Or is there another cheap/free tool that
can be used to make panels out of disjoint Gerber files?

What is WinBoard? It is a PCB layout package that runs on
Windows. (I'm using Win95) Reasonably powerful, though
mildly buggy (anyone who has hung around design automation
software for any length of time will not be surprized at
that... :-/ ...) Seems like a nice package for the
hobbyist, as you pay for the capacity that you want...
you buy it "by the pin". A limited capacity version is
available for download at http://www.ivex.com/
This is *not* intended to be a review, a testimonial,
or a flame -- until I've either fabbed some boards
or given up I wouldn't think of writing any of the above.

Be careful with those multi-channel 49MHz walkie talkies. I've not seen the insides or the schematic for one, but someone posted some information about them some time back, I think in this newsgroup, saying that they were synthesized units. He also indicated that there did not seem to be a way of modifying them for a new frequency range. If I remember correctly, it was some guy in Ontario. I can't remember his call or his name, and while he did post here quite a bit back then, I've seen no sign of him lately.

The single channel units are a different matter, as long as you get the more expensive ones that use a superhet receiver. I've not tried it, but there is nothing in them that prevents them from being moved to the six meter band. Two crystals, and some retuning should do it. Since they aren't meant to be tuned, you might need to lower the capacitance across the coils, or change the coils to make them work on six.

Yes it can be done with just one op-amp and a PCB
the size of the RS232 connector. Get Hamcomm (see below)
there is a schematics inside for simple and more complex
interfaces.

http://oak.oakland.edu:8080/pub/hamradio/arrl/bbs/programs/hamcom31.exe

There is also on the Web someone selling some cheap interfaces for
Hamcomm (never tested one but must be a one op-amp solution too)

Yes they're called Pencil Tubes and they were used in portable
electronics. They have no practical use now that I have been able to
find. I had a bunch of them and some of them are quite expensive retail
but no one will buy them. I tried for months and never got anyone
interested so I dumped them at a ham fest in a package deal with a bunch
of other tubes that are not in demand.

My shortwave reception is shotto hell because of RFI from TV sets, 4.5
MHz, EMI from the flyback and horizontal circuitry, etc. Then there is
the RFI from all the computers around me. It's sure hard to receive
decent signals on any receiver below 30 MHz.

I think you can get the headset units from Fair Radio. They should have the batteries too. I
think these units put out about 100 mW. They are popular with paintball enthusiasts. If anyone
get crystals made for the RS units please ask for the specs on the crystals and post it here.
It would be easier when ordering crystals for these radios. I like the sound of the RS units,
I don't think I would go out in public with a radio helmet! I imagine the RS units operate at
a similar power level as the headset, right? Seems like a cheap way to outfit my wife and I
with a couple of 6 meter handhelds. 73 KD1NW

Try this one...have seen one built for a MUCH larger load...but should still work:

Powder the following components:
Copper
non-conductive plastic
graphite

Mix them (play with the ratios to get the correct value) and pack them into a piece of PVC pipe. Place a copper conductor through the end caps and seal the end caps on the pipe. (i.e. build a resistor from HELL).

The one I saw was actually in a 5-gallon bucket full of oil for cooling.

Jeff

A couple of suggestions

The first is a pair of selsyn units from a surplus dealer

The second and perhaps more fun is a multi turn variable resistor
and a meter used in a bridge type circuit- Junk box and theory put
into practice.

And for the more resourceful a rotary / bianary position encoder
with corresponding interface and computer software - great practice
for the digital boys out there

0h yea the low tech way is look out window

Have a great new year

There's nothing wrong with that approach. Having said that, if you
look around, I'm sure you will find someone with an old TV antenna
that they are willing to give away. You should be able to recycle
that into a 3 to 5 element 2 metre yagi.

have fun!

Woody, from what you write, it sounds like you haven't tried embedded
wildcards. Forgive me if you already know about them, but I continue
to be surprised at the number of folks that don't know about them.

Most windows users assume you can only use the * wildcard at the
beginning
and end of a word or phrase and the ? wildcard within a word or phrase.
Windows has actually borrowed from the more robust systems and will
usually
allow you to use either form anywhere in a phrase. This makes it much
easier
to construct a "reasonable" search string.

For example, one of my major interests is in construction articles. In
this case, I'd look for "*construct*" or "*build*". This would find all
the articles on "How to Construct .....", "How to Build..",
"Constructing a...", "Building a ...", etc.

Another example would be to use the asterisk between multiple partial
phrases. For example, suppose you wanted to find all the articles about
building a 2 meter receiver. You could use some of the following:

"*build*2*met*rec*ver*" or "*construct*2*met*rec*ver*"
"*build*two*met*rec*ver*" or "*construct*two*met*rec*ver*"

This would catch "How to Build..." or "Building a...", meter or metre,
and
even receiver spelled wrong (reciever :-)

> I didn't think QST would be so crude.

Yep. I'll agree it is rather simple. (I'll leave crude for something
truly horrible :-) :-)

> I am going to call QST and complain. If enough of us do, or tell them we
> won't buy it until improved, maybe, just maybe, they will offer what
> should be a free upgraded search engine with some sophistication!

Yes, by all means do call. However, rather than complain, offer
suggestions

for improvement. If enough folks offer the same ideas, the chances of seeing
it implemented are much greater.

I also wouldn't hold out for something better. I'd would suggest getting
MORE folks to buy it any try it out to get greater exposure. That is the
BEST way to get it improved.

Finally, if you take a look on the top level directory of the first disk of
each set you will find a file called QSTnnnn.DAT; where 'nnnn' is the numeric
(year) range for the CD set (i.e., 8589 or 9094). This file contains the raw
text data used to build the database. From what I can see, it contains:
an article number, article title, column title, author's last name, author's
first name, author's call, issue year and issue month. There is also data
which appears to translate the article number to a specific image file.

If anyone wants to ask me questions about this software, feel free to
send me E-mail: pilant@seesaw.enet.dec.com.

I apologize for being so long winded, but there are probably some folks
that would benefit from these CDs; crude as they are (at the moment).

Source record: 99289

QST View - An Informal Review

by L. Mark Pilant, N1VQW

Shortly after they became available, in mid-December 1996, I ordered copies of the QST View CD sets. (Order number 5757 for the 1985 to 1989 set and number 5749 for the 1990 to 1994 set.) They arrived without incident four days later.

In my case, they were shipped in a heavy paper mailing envelope without any additional packing. However, I am concerned the jewel cases may not survive a long journey.

The Contents:

Each CD set consists of a double jewel CD case, three CDs, and a small booklet. The booklet providing some very basic instructions for installing and using the QST View software.

The first CD contains the installation software and files needed by the installation to create or add to the article database. In addition each CD contains a number of (black and white) scanned in images of the individual pages from the various issues.

Installation:

Installing the software was reasonably straight forward. In my case I was installing it on an Intel Pentium running Microsoft Windows NT Version 4.0.

The only minor problem encountered installing the 1990-1994 set was encountered when the installation attempted to install the QST View icons. A dialog box popped up indicating there was a problem adding the icons to the Program Manager. However, when the dialog box was dismissed, everything appears to be in place.

A more significant problem was encountered when I attempted to add the 1985-1989 set to the already installed 1990-1994 set. Every time, the installation would fail indicating it was unable to locate the database file; even though the file was clearly visible to the Windows NT Explorer (and at the DOS command line level).

I sent E-mail to the ARRL Technical Information Service (tis@arrl.org) and received a response about an hour later. Considering all the gateways involved between here and there, this is quite a quick turn-around.

The response, from Michael Tracy, indicated they had never tested QST View with Windows NT but they had seen this problem on Windows 95. Although they were not able to reproduce the problem, it did seem to go away after the system was rebooted. I can confirm this is also the case for Windows NT. After a reboot, I was able to successfully add the 1985-1989 set.

I later tried installed the software on a clean system in the reverse order: the 1985-1989 set first followed by the 1990-1994 set. This did not suffer from the database location failure. However, there was a slight difference in the QST View installation dialog boxes I left active which may affected the outcome.

After the installation, I started the real fun...playing with the software.

Using QST View:

As indicated in the CD booklet, the initial QST View window consists of a menu bar, a form entry area, and a document viewing area. The layout is easy to understand, but this presented the first question. How do I get the documents to view?

My first thought was to use the File pull down menu. Nope. All that lets me do is print and exit. Oh well, time to consult the on-line help. After searching a bit through the on-line help I was able to find out it was the Retrieve button which was the key. You must enter the search criteria in the form entry area and then click on Retrieve.

The retrieved articles are placed into a folder which may be viewed by clicking on the Open Folder button. (Which only appears in the menu bar when there are articles which have been retrieved.)

Retrieving the articles also cause a useful shortcut to appear. If any of the retrieved articles are contained on the currently mounted CD, the first one (on the current CD) will be brought up in the display area. Even though there may be previous articles in the retrieved article list.

All of the retrieving made a deficiency in the QST View software show up: CD swapping. There is nothing in the retrieved article list to indicate the issue in which the retrieved article is contained. As a result, you may spend a lot of time swapping CDs to view the retrieved articles.

Additional time spend using QST View uncovered a second deficiency. The form entry area does not use Microsoft "standard" data entry accelerator keys. Using the TAB key does not advance to the next field, but ENTER does. HOME and END do not position to the beginning and end of the field, but the mouse and arrow keys do. This is fairly minor, but can cause some confusion to experienced Windows users.

Another area which could use additional documentation is use of the search criteria. While the search engine is rather simple, it does have one very powerful characteristic easily overlooked: embedded wildcards.

Most Windows users are familiar with using the asterisk wildcard at the beginning and ending of a word fragment and using the question mark character within a word. However, the asterisk may also be used to match one or more characters within a phrase. It would be most useful if the on-line help offered some examples of how to exploit this power.

Summary:

If you look at QST View as a way to acquire the information is past issues of QST with about the same search power as a paper (end of the year type) index, you will be very happy with the added features of QST View.

However, if you expect QST View to be a tool to allow complex search criteria to be used to locate articles from past issues of QST you will be very disappointed.

If I had it to do all over, would I purchase these CD sets? Without question: Yes. Will I be buying future sets? Yes. Are these for everyone? No.

Suggestions for Improvements:

I would offer the following suggestions for enhancements to the QST View software:

1) Modify the form entry areas to support the Microsoft standard accelerator keys.

2) Allow the use of boolean operators (i.e., AND, OR, NOT, etc.) as part of the search criteria.

3) Include the issue year and month information as part of the retrieved article information.

4) Add a keyword shortcut (similar to "issue" or "cover") to allow the table of contents and advertisers index to be easily and quickly located.

Any questions or comments may be directed to me at:

> arrangement if you'll be transmitting in conditions where corona can occur.
> A high value choke shunted to Earth works dandy for draining static.

Could you elaborate a bit on "high value choke"? I'm guessing you mean to connect it between the center conductor and a good ground...to drain off the charge. How would it work if I use the same coax for transmit and receive? I'm concerned about transmitting into a line with the choke on it. Might work fine for a seperate receive antenna...but wasn't sure about shared xmit/recv. What are your thoughts on this one?

> Polyphaser uses a
> much superior design which has a series capacitor in the inner conductor
> path.... If you don't provide a DC shunted load, however,
> the AD and Lynics suppressors work fine.

Thanks for the info on this issue. I imagine the series capacitor will work fine on xmit, but are there higher insertion losses on recv from using this style of suppressor?

I'm fairly sure my antennas are higher impedance sources (G5RV and log periodic) so they aren't like a low impedance antenna (a loop). But what did you mean by the comment "If you don't provide a DC shunted load..." ? Was that also in reference to a low impedance antenna configuration? If so, I'm still in good shape there as well.

Again, thanks for your info and insights!

Try some electric base-board heaters. I have some that are 1Kw at 240vac.
They are linear and about 4 feet long, nice big fins to get rid of the
heat. There are actually 2 500 watt elements in each heater wired in
parallel.

If I recall right, that was in the April 62 or 63 issue Joe. Read it
carefully.

In the following April issue, they had a passive electron accelerator that
screwed into the transmission line. It used a large diameter conductor
that tapered into a narrow exit wire.

The idea is to copy a hose nozzle. The lazy electrons in the big conductor
would bunch up and squirt out the small opening. The velocity would
increase, and so the voltage would go up. The same current would flow, and
at higher voltage. So power would increase without any external power
source.

If you collect all the April QST's from the 60's, you will find many
articles of things that were wonderful ideas but never quite caught on.
They key is it's mostly in the April issues.

I saw these tubes in war surplus sonobouys (an anti-submaraine warfare device
dropped from an aircraft) in the early 1960's. These were driven from a salt
water activated battery.

4415. Electrolytic Capacitors

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-28 00:00:00 UTC
From: John Lockhart <jlockj@minn.net>
Message-ID: <01bbf4ff$6384b560$39c99dcc@default>
Source record: 99144

I bought some surplus 470 uF 450 VDC Rubycon electrolytic capacitors recently and have a couple of questions on using them.

I don't see a vent hole/plug - do they vent up ("blow their top) or down?

I'm amazed at their small size (about 1 3/4" H by 1 1/4" Diam). Is this a typical package size for 470 uF at 450 V nowadays?? (want to leave room for replacement in future)

Thanks for your help. I don't want to build them into a project/ repair incorrectly.

73,

John W0DC

$
I was once a doubting Thomas also, one who never thought any of those
schemes worked or where even legal. But after hearing so much about it
and
all those testimonials I thought HEY, WHY NOT TRY! And I did. After 2
week
I received several thousand dollars. After four weeks my local mailman
suggested if I am going to expect such a volume of mail I should open a
post office box, A LARGE ONE! Now with the Internet this money making
idea
gets even better. Why do you see so many of these get rich quick messages
on the Internet? IT REALLY WORKS. Besides whats $5, Consider it an
investment. Take this advice, if it doesn't recover your time and money,
don't try it again.

Testimonials from others who have tried this idea have reported FANTASIC
results. Markus Valppu says he made $53,664 doing this, Dan Stepstone
made
$17,000 in this perfectly legal and simple plan.

****
This works, I did it and have already received $682.00 in the past week.
****
Hello! I've got some awesome news that I think you need to take two
minutes to read if you have ever thought "How could I make some
serious cash in a hurry???" , or been in serious debt, ready to do
almost anything to get the money needed to pay off those bill
collectors. So grab a snack, a warm cup of coffee, or a glass of your
favorite beverage, get comfortable and listen to this interesting,
exciting find!
Let me start by saying that I FINALLY FOUND IT! That's right!. I
found it! And I HATE GET RICH QUICK SCHEMES!! I hate those schemes
like multi-level marketing, mail-order schemes, envelope stuffing
scams, 900 number scams... the list goes on forever. I have tried
every darn get rich quick scheme out there over the past 12 years. I

somehow got on mailing lists for people looking to make money (more like 'desperate stupid people who will try anything for money!'). Well, when I was a teenager, these claims to 'get me rich quick' sounded irresistible! I would shell out $14.95 here, $29.95 there, $24.95 here, and another $49.95 there. I had maxed out my new Circuit City Card AND my Visa...I was desperate for money!! So, I gave them all a chance but failed at every one of them! Maybe they worked for some people, but not for me. Eventually, I just tossed that JUNK MAIL in the trash when I got the mail. I recognized it right away. I can smell a money scam from a mile away these days, SO I THOUGHT.... I thought I could sniff out a scam easily. WAS I WRONG!! ....I LOVE THE INTERNET!!!

I was scanning thru a NEWSGROUP and saw an article stating to GET CASH FAST!! I thought..."Here on the Internet?? Well, I'll just have to see what schemes could possibly be on the internet." The article described a way to MAIL A ONE DOLLAR BILL TO ONLY FIVE PEOPLE AND MAKE $50, 0000 IN CASH WITHIN 4 WEEKS! Well, the more I thought about it, the more I became very curious. Why? Because of the way it worked AND BECAUSE IT WOULD ONLY COST ME FIVE DOLLARS (AND FIVE STAMPS), THAT'S ALL I EVER PAY....EVER!!

Ok, so the $50,000 in cash was maybe an tough amount to reach, but it was possible. I knew that I could at least get a return of $1,000 or so. So I did it!! As per the instructions in the article, I mailed out ('snail mail'for you e-mail fanatics) a single dollar bill to each of the five people on the list that was contained in the article. I included a small note, with the dollar, that stated "Please Add Me To Your List." I then removed the first position name of the five names listed and moved everyone up one position, and I put my name in position five of the list. This is how the money starts rolling in! I then took this revised article now with my name on the list and REPOSTED IT ON AS MANY NEWSGROUPS AND LOCAL BULLETIN BOARD MESSAGE AREAS THAT I KNEW. I then waited to watch the money come in...prepared to maybe receive about $1000 to $1500 in cash or so.... But what a welcome surprise when those envelopes kept coming in!!! I knew what they were as soon as I saw the return addresses from people all over the world-Most from the U.S., but some from Canada, even some from Australia! I tell you, THAT WAS EXCITING!! So how much did I get in total return? $1000? $5000? Not even!!! I received a total of $23,343!!! I couldn't believe it!!

I now have a brand new black Acura Integra to speak for, due to this!! Now after almost 8 months, I am ready to do it again!!! So maybe it was possible to get $50,000 in cash, I don't know, but IT COMPLETELY DEPENDS ON YOU, THE INDIVIDUAL! You must follow through and repost this article everywhere you can think of! The more postings you achieve will determine how much cash will arrive in your very own mailbox!! It's just too easy to pass up!!!

Let's review the reasons why you should do this: The only cost factors are for the five stamps, the 5 envelopes and the 5 one dollar bills that you send out to the listed names by snail mail (US Postal Service Mail). Then just simply repost the article (WITH YOUR NAME ADDED) to all the newsgroups and local BBS's you can. Then sit back and, (ironically), enjoy walking (you can run if you like! :o) down your driveway to your mailbox and scoop up your rewards!! We all have five dollars to put into such an easy effortless investment with SPECTACULAR REALISTIC RETURNS OF $15,000 to $25,000 in about 3-5 weeks! So HOLD OFF ON THOSE LOTTERY NUMBERS FOR TODAY,EAT AT HOME TONIGHT INSTEAD OF TAKEOUT FROM McDONALDS AND INVEST FIVE DOLLARS IN THIS AMAZING MONEY MAKING SYSTEM NOW!!! YOU CAN'T LOSE!!

So how do you do it exactly, you ask? I have carefully provided the mostdetailed, yet straightforward instructions on how to easily get this underway and get your cash on its way. SO, ARE YOU READY TO MAKE SOME CASH!!!?? HERE WE GO!!!

*** THE LIST OF NAMES IS AT THE END OF THIS ARTICLE. ***

OK, Read this carefully. Get a printout of this information, if you like, so you can easily refer to it as often as needed.

INSTRUCTIONS:

1. Take a sheet of paper and write on it the following: "Please add my name to your list". This creates a service out of this money making system and thus making it completely legal. You are not just randomly sending a dollar to someone, you are paying one dollar for a legitimate service. Make sure you include your name and address. I assure you that, again, this is completely legal! For a neat little twist, also write what slot their name was in: "You were in slot 3", Just to add a little fun! This is all about having fun and making money at the same time!

2. Now fold this sheet of paper around a dollar bill ,(no checks or money orders), and put them into an envelope and send it on its way to the five people listed. The folding of the paper around the bill will insure its arrival to its recipient. THIS STEP IS IMPORTANT!!

3. Now listen carefully, here's where you get YOUR MONEY COMING TO YOUR MAILBOX. Look at the list of five people; remove the first name from position one and move everyone on the list up slot one on the list. Position 2 name will now move to the position 1 slot , position 3 will now become position 2, 4 will be be 3, 5 wil be 4. Now put your name, address, zipcode AND COUNTRY in position 5, the bottom position on the list.

4. Now upload this updated file to as many newsgroups and local bulletin boards' message areas & file section as possible. Give a catchy description of the file so it gets noticed!! Such as: "NEED FAST CASH?, HERE IT IS!" or "NEED CASH TO PAY OFF YOUR DEBTS??", etc. And the more uploads, the more money you will make, and of course, the more money the others on the list will make

too. LET'S ALL TAKE CARE OF EACH OTHER BY BEING HONEST AND BY PUTTING FORTH 120 PERCENT INTO THIS PROFITABLE & AMAZING SYSTEM!!! You'll reap the benefits, believe me!!! Set a goal for the number of total uploads you'll post, such as 15-20 postings or more! Always have a goal in mind!!! If you can UUE encode the file when uploading, that will make it easier for the people to receive it and have it downloaded to their hard drive. That way they get a copy of the article right on their computer without hassles of viewing and then saving the article from the File menu. Don't alter the file type, leave it as an MS-DOS Text file. The best test is to be able to view this file using Microsoft's Notepad for Windows 3.x or WordPad for Windows '95. If the margins look right without making the screen slide left or right when at the ends of the sentences, you're in business!

5. If you need help uploading, simply ask the sysop of the BBS, or "POST" a message on a newsgroup asking how to post a file, tell them who your Internet provider is and PEOPLE WILL ALWAYS BE GLAD TO HELP. I would try to describe how to do it but there are simply too many internet software packages with slightly different yet relatively simple ways to post or upload a file. Just ask for help or look in the help section for 'posting'. I do know that for GNN, you simply select 'POST' then enter a catchy description under the subject box, choose 'ATTACH', selecting 'UUE' and NOT 'TXT', then choose 'Browse' to go look for the file. Find your text file CASH.TXT and click on it and choose 'OK'. Place a one line statement in the main body section of the message post screen. Something like "Download this to read how to get cash arriving in your mailbox with no paybacks!" or whatever. Just make sure it represents its true feasibility, NOT something like..."Get one million dollars flooding in your mailbox in two days!"

You'll never get ANY responses!

6. And this is the step I like. JUST SIT BACK AND ENJOY LIFE BECAUSE CASH IS ON ITS THE WAY!! Expect to see a little money start to trickle in around 2 weeks, but AT ABOUT WEEKS 3 & 4, THE MONEY STORM WILL HIT YOUR MAILBOX!! All you have to do is take it out of the mailbox and try not to scream too loud (outside anyway) when you realize YOU HIT THE BIG TIME AT LAST!!

7. So go PAY OFF YOUR BILLS AND DEBTS and then get that something special you always wanted or buy that special person in your life (or the one you want in your life) a gift they'll never forget. ENJOY LIFE!

8. Now when you get low on this money supply, simply re-activate this file again; Reposting it in the old places where you originally posted and possibly some new places you now know of. Don't ever lose this file, always keep a copy at your reach for when you ever need cash. THIS IS AN INCREDIBLE TOOL THAT YOU CAN ALWAYS RE-USE TIME AND TIME AGAIN WHEN CASH IS NEEDED!

People have asked, "What if the plan is played out and none sends you
any money?" So what! What are the chances of that happening when there
are tons of new honest users and new honest people who are joining the
Internet everyday and are willing to give it a try?!? Estimates are
20,000 to 50,000 new users EVERYDAY!!! Remember, play FAIR and HONEST,
and THIS WILL WORK, I PROMISE YOU!!! You just have to be honest. Make
sure you print this article out RIGHT NOW! ! ! Also, keep a list of
everyone
who sends you money and always keep an eye on the newsgroups postings to
make sure everyone is playing fair.

FINAL THOUGHT
In order for this system to work and remain legal, you have to follow the
steps and send your $5. Honesty is always the best policy. Good luck,
have fun and make some serious money!!!!!

Proof:
This arraignment does not constitute a "chain letter" under US Title 18
Code section1302. Because you are purchasing a service.

Yep thats a normal size for a cap of that type now-a-days and on
a chassis mount type they will vent thru the + terminals...same
with the PC mount ones that i have seen lately.

>Timothy
>KD4IKY

Well, lets see what you need. For mode U/V (the old mode B), you'll need a 70cm Tx and a 2m Rx. Now an easy way to get these is with transverters from a 10m rig (or an old SSB CB). The latter can be had cheap if you don't already have something for 10m. You don't have to convert it, you can choose the crystals in the transverters to go direct to and from CB frequencies. You'll want to mod it to allow enough RIT range to cover between channels, and to allow XIT as well. This is usually pretty easy to do. Down East Microwave sells suitable transverter kits, or you can build from scratch based on the designs in the RSGB VHF/UHF Dx Book. A preamp will be needed, and the ARRL Handbook and the Proceedings of the Central States VHF Conference (available from ARRL) have several suitable designs.

Another approach is to build a 2m Rx and 70cm Tx. The Rick Campbell R2 and T2, described in a QST series and in newer Handbooks, are suitable for this. Kanga sells kits, but these radios are simple enough to build dead bug style. The R2 and T2 are universal designs which can be made to work from LF up through UHF (up to 500 MHz anyway). They use the phasing method to generate SSB and to obtain single signal reception. You have to supply the LO. A VXO and multiplier should do fine. You can find suitable VXO designs in the Handbook. A good mast mount preamp will be required for receive, and any of the ones referenced above should work fine. You'll need a PA for the Tx. RF Parts sells suitable brick amps, as does Down East Microwave. Depending on antenna gain, you'll need from 10 watts to 100 watts uplink power. Err on the side of too much, you can turn it down if you wind up louder than the beacon.

(Note that you can set the R2 and T2 up for 10m and use transverters, as with the CB set recomendation above, if you prefer. There are some advantages to this approach, though it adds some complexity and cost.)

If you'd like to try your hand at digital via the satellite. A suitable receiver for 9600 baud on P3D and the Microsats can be made from a GE UHF Exec II or Mastr II receive strip. Use the temperature compensation input of the Icom (channel element) for doppler tracking. These Rx strips can be found at hamfests for $25, or $50 for a complete radio. The UHF Tx strip can be used as a CW transmitter for mode U/V as is. With 80 watts output, they do great. For data uplink, a VHF version of the Tx strip can be modified for 9600 baud. Disable the PM modulator and use the temperature compensation input to the Icom for modulation (or rewire to use a Motorola channel element and modulate that, it's a bit more linear).

If you prefer to scratch build the FM setup, a receiver based on the MC13135 receiver subsystem chip, and a Tx based on the MC2833 exciter chip, are pretty easy to do. Add a power brick from RF Parts, and you're on your way. Converting the business band radios is so easy and cheap, though, it is really the better way to go.

P3D will have many more modes. Setting up for them will require either more transverters or more radios. Mode U/V and the Microsat style 9600 baud digital mode will likely the be the most popular in the beginning, however, because everyone equipped for Oscar 10 and Oscar 13 will already be set for mode U/V and all the Microsat ground stations will be set for 9600 baud data.

You'll need a pair of steerable yagis or helixes, for mode U/V. You can build these yourself and save a bunch of money. When the sat is near apogee, it hangs in virtually the same spot in the sky for long periods, so you can aim the antennas by hand, no need for auto-tracking, or even for rotators. The antennas don't have to be very high off the ground, since they are looking up. You can use a tripod or post mount and turn them directly by hand as needed. The antennas can be made from a length of 2x2 and use aluminum clothesline wire for elements. There are a number of antenna programs available on the net which can optimize the design for you.

It doesn't have to cost gobs of money to get on the satellites if you use a little ingenuity. You can be on the digital birds for under $100, or on U/V SSB for a bit over $300, if you scrounge and adapt a bit.

Steve
If you are using stepper motors consider the UCN5804, available from alltronics for $4.50 I think. It will drive a unipolar stepper with over an amp and I think up to 40 volts.
If you're using DC servo motors, check out tje PIC-SERVO/PIC-ENC chip set from JR Kerr. All the data is available on the web. They will control just about any motor driver you can come up with including national's LMD series and any of the commercial servo amps. Email adress is dcservo@aol.com
Hope this helps or at least gets you started in a new direction.

Or, go to a good hardware store in your area. Find one of those
battery operated door bells with the remote control(RF) push button.

Get one of the cheap ones, they cost apx $10.00.

Remove the bell/buzzer and replace it with a
transistor + relay + misc , presto!

Ted...
(The one I got here in front of me is made by Nutone)

Cross-posted to: rec.radio,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.cb,rec.radio.scanner

The following list will be included in the Jan '97 release of the FAF.
Any comments or corrections would be greatly appreciated. (The FAF lists
specific U.S. frequencies and channels in various bands of interest to
scanner listeners.)

From the FAF - Frequently Asked Frequencies
on ftp://oak.oakland.edu
as /pub/hamradio/docs/misc/scanner.faf

CTCSS (PL) Frequencies

Freq (Hz)	Designator EIA	Ham	Freq (Hz)	Designator EIA	Ham	Freq (Hz)	Designator EIA	Ham
67.0	L1	01	110.9	2Z	15	179.9	6B	29
71.9	L2	02	114.8	2A	16	186.2	7Z	30
74.4	WA	03	118.8	2B	17	192.8	7A	31
77.0	L3	04	123.0	3Z	18	203.5	M1	32
79.7	SP	05	127.3	3A	19	206.5	8Z	
82.5	L4	06	131.8	3B	20	210.7	M2	33
85.4	YA	07	136.5	4Z	21	218.1	M3	34
88.5	L4A	08	141.3	4A	22	225.7	M4	35
91.5	ZZ	09	146.2	4B	23	229.1	9Z	
94.8	L5	10	151.4	5Z	24	233.6	M5	36
97.4	ZB	11	156.7	5A	25	241.8	M6	37
100.0	1Z	12	162.2	5B	26	250.3	M7	38
103.5	1A	13	167.9	6Z	27	254.1	OZ	
107.2	1B	14	173.8	6A	28			

Motorola differs from EIA with: XZ (L1), XA (L2), XB (L3),
YZ (L4), YB (L4A), ZA (L5). ICOMM does not use 97.4 and uses one
less than the amateur numbers above that (i.e. ICOM #25 = 162.2).

These are "sub-miniature" or pencil tubes. The 5840 and 5636
are used in the RCA SRR-11/12/13 & 13A receivers. Can't really
help with the others.

These tubes are little preamp triodes and pentodes. Sure, they can
still be used, just like their bigger brothers. Not all tube handbooks
have data on them, but it is not impossible to find. Most operate in
convential circuits, but usually with lower maximum ratings compared
to bigger tubes.

The GE ESSENTIAL CHARACTERISTICS book reprinted and sold by Antique
Electronic Supply lists data on these types.

I've bought 3 scanners from Pawnshops and have always gotten good prices
and good products. They take them only if they work properly, because they
don't want to lose their collateral if the units don't work. Also, most
people that pawn their equipment don't intend to lose their items, but just
don't have the money to get it back. I'm on very friendly terms with three
pawnshops in my area, and they will let me know if they have something I
might be interested in. One even has ham gear once in a while. If it were
me, I would grab that scanner before someone else does!

Hi,

I have written a window's based DTMF decoding program. The program requires a DTMF decoding chip (M8870) be connected to the printer port of the computer.

The schematic diagram is part of the program and is very easy to construct. If interested, please email me for a copy of the demo.

The demo decodes all the tones without limit. It does not save the tone to a file on the hard drive.

4438. Telecommunications Act of 1996

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-28 00:00:00 UTC
From: J Mullins <jmullins@erols.com>
Message-ID: <01bbf47d$243282c0$276e60cf@jmullins.erols.com>
Source record: 99220

The FCC, on August 5, !996 adopted a rule which partially pre-emts the enforcement of community association restrictions with respect to satellite dish antennas, broadcast television antennas, and other communication reception devices.

The above statement is the leading sentence of a memo sent to the Board of Directors of my community's Home Owners Association.
I will try to convey the main points.

"Under the new rule, any association Covenant, rule, or similar restriction which "impairs" the installation, maitenence or use of certain antenas is UNENFORCEABLE."

Antennas protected include dishes up to one meter and any size antenna designed to recieve television broadcast services.

The FCC rule allows communities to regulate antennas so long as the restriction does not "impair" the installation, maitenence or use of the antenna.

HOA's can regulate the placement of antennas so long as the reception would not be compromised

If you use the heaters as-is, you'll have a problem with their inductive reactance - small but easily avoidable. Place a variable capacitor in series with them and tune for minimum SWR. I've used this with light bulbs and other odd loads and it works like a charm.

Those are "sub-miniature" tubes. Mostly used in military radios
in the late 50's early 60's. Look at my web page:

http://www.netcom.com/~wa2ise/radios/penciltubes.html

for info on the ones you mentioned above, and likely others you
have.

If you don't need them, I would be interested in them. my e-mail

>NEVER stated ANYTIHNG as fact that was not widely known to be fact.
>Anything that was speculative was clearly stated as such.

Although I had a general respect for Dr. Sagan, and mourn his passing,
I must say your defense is a bit too vigorous. Dr. Sagan pulled several
boners in his published works. We can't really hold his now infamous
nuclear winter theory against him, though in retrospect it is obvious
where he went wrong. At the time there wasn't any hard data to show
his aerosol dwell time assumptions were off by orders of magnitude.
He based his assumptions on the behavior of Martian dust storms and
naively applied them to Earth's atmosphere. It took the Kuwaiti oil
fires to demonstrate the fallacy of that. The presence of water vapor
in Earth's atmosphere, but virtually absent in the Martian atmosphere,
makes the difference, causing the aerosols to quickly rain out. But he
pulled a real howler in The Dragons of Eden when he calculated that
the information rate of the human visual system tops out at 5,000 bps.

He based that on the assumption that the human visual system can only
handle a 2500 pixel area of 20 bit color depth once every 10 seconds.
Anyone at all familiar with television or movies would instantly know
that's absurd. In a 10 second commercial, the eye has to process 92
million pixels at an equivalent color depth of 24 bits. And advertisers
pay big money for high quality productions because the eye *can* do that.
If Dr. Sagan were right, advertisers could save big money by using cheapy
VHS equipment to produce their 10 second ads. In fact if he were right,
a 10 second ad would have no impact at all since he claimed it takes
that long just to absorb a 2500 pixel segment of one frame.

The now outlawed practice of subliminal advertising demonstated
that the eye can process a 307,000 pixel image of 24 bit color
depth in 1/30th of a second to the extent of influencing purchasing
decisions. That's a data rate of 220.8 Mbit/sec. And that one fact,
known since at least the 1950s, blows his entire chapter two thesis
on the nature of memory storage in the brain into a cocked hat.

A choke of several millihenries, or a high value resistor, either of
which have a high impedance at HF compared to the 50 ohm line they
are shunting, will drain static, a DC phenomenon, while being virtually
invisible to the RF system. The choke, or resistor, should have no
effect on transmission or reception.

>> Polyphaser uses a
>> much superior design which has a series capacitor in the inner conductor

>work fine on xmit, but are there higher insertion losses on recv from using
>this style of suppressor?

No. The value of the capacitor is sufficient to present a negligible
impedance to HF RF. If this weren't so, it would affect transmit.
Most HF receivers are voltage driven, not power driven, and aren't
fussy about the match presented to them.

> I'm fairly sure my antennas are higher impedance sources (G5RV and log
>periodic) so they aren't like a low impedance antenna (a loop). But what
>did you mean by the comment "If you don't provide a DC shunted load..." ?
>Was that also in reference to a low impedance antenna configuration? If so,
>I'm still in good shape there as well.

On receive, the *receiver* is the load presented to the line, not the
antenna. I was talking specifically about cavity resonators where the
input loop is DC shorted. However, some receivers use a shunt coil
in their inputs, and that would have a similar, though not so pronounced,
effect.

>Timothy
>KD4IKY

Well, lets see what you need. For mode U/V (the old mode B), you'll need a 70cm Tx and a 2m Rx. Now an easy way to get these is with transverters from a 10m rig (or an old SSB CB). The latter can be had cheap if you don't already have something for 10m. You don't have to convert it, you can choose the crystals in the transverters to go direct to and from CB frequencies. You'll want to mod it to allow enough RIT range to cover between channels, and to allow XIT as well. This is usually pretty easy to do. Down East Microwave sells suitable transverter kits, or you can build from scratch based on the designs in the RSGB VHF/UHF Dx Book. A preamp will be needed, and the ARRL Handbook and the Proceedings of the Central States VHF Conference (available from ARRL) have several suitable designs.

Another approach is to build a 2m Rx and 70cm Tx. The Rick Campbell R2 and T2, described in a QST series and in newer Handbooks, are suitable for this. Kanga sells kits, but these radios are simple enough to build dead bug style. The R2 and T2 are universal designs which can be made to work from LF up through UHF (up to 500 MHz anyway). They use the phasing method to generate SSB and to obtain single signal reception. You have to supply the LO. A VXO and multiplier should do fine. You can find suitable VXO designs in the Handbook. A good mast mount preamp will be required for receive, and any of the ones referenced above should work fine. You'll need a PA for the Tx. RF Parts sells suitable brick amps, as does Down East Microwave. Depending on antenna gain, you'll need from 10 watts to 100 watts uplink power. Err on the side of too much, you can turn it down if you wind up louder than the beacon.

(Note that you can set the R2 and T2 up for 10m and use transverters, as with the CB set recomendation above, if you prefer. There are some advantages to this approach, though it adds some complexity and cost.)

If you'd like to try your hand at digital via the satellite. A suitable receiver for 9600 baud on P3D and the Microsats can be made from a GE UHF Exec II or Mastr II receive strip. Use the temperature compensation input of the Icom (channel element) for doppler tracking. These Rx strips can be found at hamfests for $25, or $50 for a complete radio. The UHF Tx strip can be used as a CW transmitter for mode U/V as is. With 80 watts output, they do great. For data uplink, a VHF version of the Tx strip can be modified for 9600 baud. Disable the PM modulator and use the temperature compensation input to the Icom for modulation (or rewire to use a Motorola channel element and modulate that, it's a bit more linear).

If you prefer to scratch build the FM setup, a receiver based on the MC13135 receiver subsystem chip, and a Tx based on the MC2833 exciter chip, are pretty easy to do. Add a power brick from RF Parts, and you're on your way. Converting the business band radios is so easy and cheap, though, it is really the better way to go.

P3D will have many more modes. Setting up for them will require either more transverters or more radios. Mode U/V and the Microsat style 9600 baud digital mode will likely the be the most popular in the beginning, however, because everyone equipped for Oscar 10 and Oscar 13 will already be set for mode U/V and all the Microsat ground stations will be set for 9600 baud data.

You'll need a pair of steerable yagis or helixes, for mode U/V. You can build these yourself and save a bunch of money. When the sat is near apogee, it hangs in virtually the same spot in the sky for long periods, so you can aim the antennas by hand, no need for auto-tracking, or even for rotators. The antennas don't have to be very high off the ground, since they are looking up. You can use a tripod or post mount and turn them directly by hand as needed. The antennas can be made from a length of 2x2 and use aluminum clothesline wire for elements. There are a number of antenna programs available on the net which can optimize the design for you.

It doesn't have to cost gobs of money to get on the satellites if you use a little ingenuity. You can be on the digital birds for under $100, or on U/V SSB for a bit over $300, if you scrounge and adapt a bit.

>too much expertize. I've made a simple groundplane with a chasis mount
>and a couple of wire coathangers, and I'd like a yagi equally as cheap.

Sure. You can make a yagi from a length of 2x2 and some aluminum
clothesline wire. The wire is stiff enough to form elements. Just
drill the 2x2 and insert the wires where you want elements. You
can use PVC pipe as a boom too, but spar varnished wood 2x2 lasts
better in the sunlight than PVC. It's cheaper and easier to work
with too. Any of the yagi design programs floating around the
net will give you the dimensions and spacings for the elements.
Note that spacings will be different for a non-conductive boom
than for a metal boom. Make sure the program knows how to handle
this.

>????????

The BP3 is *not* a rapid charge pack. You must use a *constant current*
source and set the current for 40 mA. A 3 terminal regulator can be
configured to act as a constant current source. The voltage used is
unimportant as long as it is high enough to allow the regulator to
maintain a 40 mA charging rate into the battery. Charge for 14 hours
to fully recharge the depleted pack.

ï¿½ Other than an obnoxious negative temperature coeficent (from the
enclosed mixture building up pressure, and acting like a carbon granule
microphone
from an old telephone), how you gonna dissipate ~27000 or so BTU/Hr
through
1 or 2 sq. ft. of PVC plastic ï¿½" thick? We're talking enough heat to
bring 5
gallons of water from room temperature to boiling in about 12 minutes
(if
I did the math right). And oil heats even faster, due to lower specific
heat.
How long do you need to dissipate this power for?

> The one I saw was actually in a 5-gallon bucket full of oil for cooling.

ï¿½ You can expect to see gobs of rehardened PVC floating on the surface
of that 5 gallon bucket. Yes, they'll float, from all the trapped
bubbles
of clorine gas liberated in the fire. :)

However, if you pack it into some sort of long ceramic pipe, it might
work.

> >good as an RF load.
> >
> >Gary Tait , VE3VBF

ï¿½ How about some fairly thick bare nichrome wire supported from some ceramic
structure, hanging down in a zig-zag pattern, in an oil-filled 55 gallon drum? If you zig-zag carefully, you can keep the inductance down quite low,
where it might be acceptable at 300Khz, depending on your needs. Besides,
the capacitance of a grounded metal drum just might balance it out. :)

Also, IMHO, at 2Kv, water is not a safe option due to the shock hazard.

Technically, these should be referred to as subminiatures and not
"pencil tubes". The term "pencil tube" is usually applied to a series of
UHF tubes developed by RCA which are not necessarily small, but are tall
and thin. Types include 5675, 5794, 5876, 5893, 6263, and 6562.

I use a resistor to bleed the charge on my 70 foot vertical. Before I added the bleeder resistor, during windy weather, the charge on the vertical would arc over a 3500v air variable tuning capacitor about every half minute. I prefer resistors to chokes because chokes have internal self resonances and resistors don't.

Cutoff frequency (-3 dB) for a single RC section is 1/(2*pi*R*C), where the
frequency is in hertz, C in farads, R in ohms.

Be advised, when creating a yagi antenna with wire on a wooden frame:
even tho it is a valid approach, the bandwidth of the antenna is
directly affected by the diameter of the wire used.
It is better to use tubing, and I have made several using tips from the
antenna book (ARRL) and old Television antennae Low channels yield
longer source stock, and aluminum conduit for the boom (don't go over
5-6 elements or it becomes unwieldy) and long self-tapping screws to
hold the elements to the boom.
for the gamma match: I used a piece of stripped coax inserted into the
end of the gamma element for the series capacitor, and slid the tube
back and forth to tune it.
I had good results until Hurricaine Hugo remodeled my farm ... now
nothing.

Hi Dave and Gary,

In article <1996Dec28.060742.3631@ke4zv.atl.ga.us>, gary@ke4zv.atl.ga.us (Gary Coffman) writes:

>A choke of several millihenries, or a high value resistor, either of
>which have a high impedance at HF compared to the 50 ohm line they
>are shunting, will drain static, a DC phenomenon, while being virtually
>invisible to the RF system. The choke, or resistor, should have no
>effect on transmission or reception.

A several millihenry choke may not have a high impedance at HF. It likely will have series resonances that render it useless as a choke on some HF frequencies. A 100 microhenry choke would be more than enough impedance, about 1000 ohms on 160, and much less prone to unwanted resonances. Use a choke of 50 to 100 microhenries.

>> Thanks for the info on this issue. I imagine the series capacitor will
>>work fine on xmit, but are there higher insertion losses on recv from using
>>this style of suppressor?
>
>No. The value of the capacitor is sufficient to present a negligible
>impedance to HF RF. If this weren't so, it would affect transmit.
>Most HF receivers are voltage driven, not power driven, and aren't
>fussy about the match presented to them.

Most HF receivers are power driven. They have a finite receive input impedance, and it is almost always between 20 and 100 ohms in most rigs. That requires power, not voltage alone. To require "voltage", the input impedance woiuld be near infinite.

If the capacitor passes HF RF, then I suspect it is almost useless for lightning. It would only be effective at VLF frequencies and lower as an isolating device. Lightning and nearby stroke induced EMF has a rise time that is very fast, so the cap looks like it is not even there.

>On receive, the *receiver* is the load presented to the line, not the
>antenna. I was talking specifically about cavity resonators where the
>input loop is DC shorted. However, some receivers use a shunt coil
>in their inputs, and that would have a similar, though not so pronounced,
>effect.

Protecting an HF receiver, via a surge suppressor that will carry kilowatts of RF, is wishful thinking. As little as 50 volts of surge for a few microseconds can ruin a receiver's front end. It's best to disconnect antenna and main connections when the equipment is not in use. A simple T

network antenna tuner or high pass or band pass filter would do much more than any of these gas tube gimmicks for protecting a receiver. A pair of clamp diodes and a fuse link, plus a hardened front end would be better than transmit type surge suppressors.

Ian,

I agree with everything you said except this.

The real inventor was Chuck Collingwood. He did this for the mitary in the early 40's or 50's. He used them in a military repair depot, to do quick connections to test equipment. He didn't even have the outer shell on the connector, it was like an N male without the outer screw on part.

Collingwood had a real big nose, and his co-workers called him big nose Chuck. They would ask each other for one of BNC's connectors, and the name stuck even after the bayonete piece was added.

Cutoff frequency (-3 dB) for a single RC section is 1/(2*pi*R*C), where the
frequency is in hertz, C in farads, R in ohms.

> 73 de va3rr/aa8lu
Be advised, when creating a yagi antenna with wire on a wooden frame:
even tho it is a valid approach, the bandwidth of the antenna is
directly affected by the diameter of the wire used.
It is better to use tubing, and I have made several using tips from the
antenna book (ARRL) and old Television antennae Low channels yield
longer source stock, and aluminum conduit for the boom (don't go over
5-6 elements or it becomes unwieldy) and long self-tapping screws to
hold the elements to the boom.
for the gamma match: I used a piece of stripped coax inserted into the
end of the gamma element for the series capacitor, and slid the tube
back and forth to tune it.
I had good results until Hurricaine Hugo remodeled my farm ... now
nothing.

>de kc5itc, Joe, in Tx

If I recall right, that was in the April 62 or 63 issue Joe. Read it
carefully.

In the following April issue, they had a passive electron accelerator that
screwed into the transmission line. It used a large diameter conductor
that tapered into a narrow exit wire.

The idea is to copy a hose nozzle. The lazy electrons in the big conductor
would bunch up and squirt out the small opening. The velocity would
increase, and so the voltage would go up. The same current would flow, and
at higher voltage. So power would increase without any external power
source.

If you collect all the April QST's from the 60's, you will find many
articles of things that were wonderful ideas but never quite caught on.
They key is it's mostly in the April issues.

The key phrase that would cover amateur antennas isn't there. We usually have antennas which not ony receive but transmit. It would have been nice if the FCC had pre-empted amateur antennas from covenants and restrictions, but so far, it has not done so. Relying on that pre-emption will give an amateur a sinking feeling if the homeowner's association or municipality or whatever is being sued has a competent atty. The communications acts of 1996 have been an almost unmitigated disaster for amateurs so far. Congress mandated sale of amateur frequencies, and we got nothing in return for example. -art clemons-

If you're near a Fry's Electronics (Northern & Southern Calif) you could
pick up a DTMF encoder/decoder kit and use that. I think they also have
transmitter/receiver pairs used for remote control. The kits run around
$30 and come with PCBs.

Buy it! You might even try to talk them down a few bucks. Believe it
or not, I was able to find the same scanner for $100 also at a pawn
shop. I think they must have mistaken it for an older model since it
was a lower number than they were used to seeing. They don't make this
type of mistake often so if you're lucky enough to catch one, grab it!

Enjoy!

Dual-band with thumbwheels might be tough, but one of the most rugged and bullet-proof high-power dual-band HTs ever built is the ICOM IC-32AT. It also is one of the last of the HTs with excellent receiver audio volume.

They come with PL encode and with the appropriate option boards, they can also be used for PL and DTMF (paging) decode. I use one as my personal HT and another as a portable base station. I have no intention of ever getting rid of them.

They are currently selling used for around $300.

In the late 60's, we built some low-noise preamps at 60 MHz using
a small tube, called a Nuvistor, I believe. They had
metal envelopes, about 3/8" by about 1 inch. They had little pins
in a base recessed in the metal envelope.

These were great little tubes.

Don, N6MCE

Hello.
I've just updated my FTV program, which does FAX & SSTV using a SoundCard, to decode Baudot using the same (FM) demodulation engine.

Here is a run down of the more interesting features:

(1) It keeps the demodulated signal in memory, so that the signal can be analysed again at a different keying rate or polarity! Garbage can be resampled on the fly, which means that minutes of received signals decoded at the wrong baud rate or keying polarity are recovered, on the fly, while still receiving.

(2) Keying rate and polarity are analysed automatically - standard baud rates are automatically set following analysis.

(3) Tuning oscilloscope available at all times, without loss of copy.

(4) Program works in real time.

(5) I wrote it, and I love it - I myself can't believe it works so well!

Download your copy of FTV from my web site, at:
http://www.geocities.com/SiliconValley/2504

System requirements, and the standard features of FTV are described in the following page:
http://www.geocities.com/SiliconValley/2504/ftv.htm

By the way, AM signals from low orbiting weather satellites are also decoded - no extra interfaces needed. Demodulation mode is user selectable in software.

Hope you all have a load of fun receiving 'words and pictures' - I hope to get some feedback !

Happy New Year 1997
All the best from Brian, 9H1JS, on the Island of Malta.

Greetings all...

I need a couple large knobs, anywhere between 2 and 2.5 in. diameter. Must be for 1/4" shaft and have a setscrew. Not picky about style. Would like two matching knobs, tho. If anyone has a couple laying around they'd be willing to part with, pls let me know. Or if anyone has a source for them, pls pass it along. I've looked in all my catalogs and other on-line sources without any luck. Lots of little ones but no big ones.

Actually, I'm trying to find the large knobs for a Johnson Matchbox tuner. I'd REALLY like to find a couple for it but will settle for a pair of large generic knobs.

Thanks, 73, & HNY... Mark AA7TA

I had a shirt pocket a.m. broadcast band radio in the 1950's that used three of them in a regenerative (Armstrong) receiver circuit. One regen detector plus two audio amps. They were common in the shirt pocket sized hearing aids of that era too. 1.5 Volt filaments and 15 volts or so on the plates. I seem to recall that the max plate voltage was about 60 volts.

Ran into them again in the 1960's servicing Collins short-wave receivers and transcievers used in large USAF aircraft such as B-50 Bombers. They were used in the VFOs. I suspect that the very low power consumption and heat was the reason they were chosen, as those VFO's were legendary for stabilizing quickly after power on and for keeping their calibration over time. The tubes were right inside the sealed VFO cylindrical container along with the tuned circuit and other VFO components.

I salvaged a few old meters from some old equipment. I would like to change the faces and hook these up to indicate power out (not looking for anything accurate, just a neat large meter needle jumping on voice/signal modulation...these are abt 6" x 9"...would look cool) Does anyone have an idea for hooking these up? Can I wrap some wire around a coax to get an indication of power out? What type of circuit can i throw together to make this work? -Gerry

Just got our electric power back this pm here in western Washington so am just reviewing the Dec 27 submissions.

The suggestion for using a baseboard electric heater caught me attention as I have one stored in the garage. But -- I would have supposed that the elements in these are wire-wound --? It so, would this not introduce a very large inductive reactance?? Tell me it ain't so.

The first air-to-air missile, the Falcon, was full of them. They were held onto circuit boards with springy metal clips (similar to large fuse clips) and hard-wired in.

The ARC-21 Automatic Direction Finder receiver (made by Aircraft Radio Corp) used between 10 and 20 of these subminiature tubes. This set was designed in the late '50s, and I know some of them still to be in use. It is beautifully designed, and I use one as my regular BCB receiver (it covers about 300 kHz to 1.8 MHz in 4 bands).

The push-pull drivers for the loop antenna are also subminiature power pentodes (I think the number is 5906), and they operate at about 6 watts dissipation (6V @ 500 ma for the filaments, 120V@30 ma plate idle). Needless to say, they go gassy quite regularly!

These tubes are a fallout from the WWII effort on proximity fuzes.

Ian, while this is probably true for the yearly QST/QEX/NCJ CDs, the QST View multi-year sets are ALL scanned. Someone (and I thank them) spent considerable time creating the index of article, column, author, etc.

> What disappointed me about the 1995 CD-ROM was that it makes no use of

> course, but all the index entries are "dead" - you can look but you
> can't click to jump directly to an identified article. Worse still, the
> Index only gives month and page numbers, and there's no way to jump
> directly to a page number. (Mark: is this the same in the new QST sets?)

There isn't any way to directly go to a particular page, but there is an indirect way. For the "Article" you specify "*issue". This will cause QST View to locate a special entry which pulls all pages for an issue except the covers. Once the issue is loaded, you can use the "Page" pull-down menu to go to a specific page. (Page 3 is usually the table of contents, and off you go from there :-)

If you select a multi-page article, the page numbering is relative to the start of the article, not the issue. For example, page 1, 2, and 3 of the article may have appeared on pages 74, 75, and 76 of the issue. QST View only allows you to reference 1, 2, or 3.

> Not if you already have the relevant QSTs and the space to store them.
> For everyone else they're well worth considering.

The CDs certainly do save space. They also allow you to purchase the back issues in 5 year blocks; rather than having to buy the entire set on micro-fiche or try and locate original copies.

However, it is worth point out again, the QST View CD sets to not allow you to search articles. All you can do is search the bibliographic information (title, author, etc.)

I am in the process of cleaning out my shop and have several (100+) owner/operator/service manuals for various pieces of Collins, Heathkit, and Drake gear. If you have any specific needs email me and I will check. Also in the pile is a Blue 3ring binder w/Collins Emblem and contains dealer pricing and brochures for the early 60's to about 71 on Collins equipment (make offer)

4508. PLEASE READ! A thought about keeping CW....

Newsgroup: rec.radio.amateur.homebrew
Date: 1996-12-30 00:00:00 UTC
From: "Ray Hodgkiss, N9YNG" <hodgkiss@kiva.net>
Message-ID: <32C84C4B.5161@kiva.net>
Source record: 99112

I know this may seem not "proper" to start a debate in this newsgroup about keeping CW as a requirement. However, I have a thought about this topic that pertains to homebrewing.

In a nutshell:

What if people were given a choice about either taking a morse test, or homebrewing a rig, a piece of equipment, or something else other than an antenna? So maybe somebody would have to homebrew a transverter for a 5 wpm code test, a HF rig for a 13 wpm code test, and an amp for a 20 wpm code test. VEs can oversee and offer minor assistance, maybe over a few weekends. (I know that the ITU requires 5 wpm for HF.)

The benefits:

It would bolster the entire homebrewing aspect of amateur radio. More kits and literature about homebrewing would appear on the market. It would also act as a more effective filter, not becasue it would prevent people from getting their licenses, rather that the assistance from VEs on the projects (to also prevent cheating) would allow the canidate and the ham radio community to get to know each other a lot better, and hence "shame" people into good operating practices.

The drawbacks:

It would involve a lot more work for everybody, VE and the person trying to get a license. However, I believe that the benefits outweigh the drawbacks.

Please, all comments are appreciated!

This is starting to become a FAQ! There is nothing wrong with your alignment. This is a known problem with the IC-245 and IC-211 2m radios, the sympton being, erratic display (uncontrollable or missing segments, etc.) and lack of tuning ability from the knob.

The problem may be fixed, but is rather time consuming and delicate! ICOM happened to use (to their infinite regret!) brass eyelets to make connections between the top- and bottom sides of the PLL circuit board. Now any metalurgist or chemist should know that brass eyelets and copper circuit traces (plus humidity) will form a small voltage (a battery, of sorts) that will eventually lead to corrosion and loss of contact between the two metals. This is what is occuring with your radio.

The fix involves opening up the PLL module (top and bottom), being very careful not to damage the myriad of wires connecting this module to the rest of the radio. The 40-pin(?) PLL IC must also be carefully removed using solder wick and the usual ESD precautions (ICOM does not have any more of these available). The eyelets are obvious and must all be removed using solder wick. As you remove each one, replace it with a small COPPER wire jumper and resolder. Take care that the wire ends don't short something out! As I recall, there are maybe 20, or so, of these eyelets; including two located under the PLL IC. Once all the eyelets have been replaced, reinstall the PLL IC and hopefully, your radio will be back in working order.

When my 245 had the same problem, ICOM also had me replace all the polystyrene capacitors in the PLL module. I don't believe doing this helped with the primary problem, however.

Good Luck!

I don't know about WWW sites, but for about $12 (US) you can get a CD
called QRZ Ham Radio that has a huge number of mods in hypertext format
(windows help format) There are several good mods for the 850 including
removing the attenuator in the AM broadcast band to improve sensitivity.
The disk also has a great callbook lookup and lots of other software.
you can find it at your next hamfest.

Good luck.

Fellow Amateurs: Please read the first two paragraphs!

CLAWSON@TELEGRAFIX.COM (PAT CLAWSON) said to ALL in comp.bbs.misc:

Boardwatch may have abandoned the BBS sysop, but TeleGrafix is still standing strong with them. However, we think that BBS systems must become Internet-connected if they are to survive in a Webbed world.

First, we need to quit calling these online systems by the moniker "BBS." The term has come to reflect something on the order of ham radio -- low-rent communications run by amateurs. That may accurately reflect some BBS systems, but we've found that many sysops run very professional online businesses.

Second, we need to start emphasizing the Power of Telnet and talk about Telnet Sites, not BBS systems. A telnettable BBS or legacy system can do many things the Web can't. Most of the computer industry and public has been Web-washed (brainwashed) by all the press hype. They think the Web is all there is to the Internet/online experience. Just a couple of days ago, I was talking to the Internet reporter for one of America's most prestigious newspapers. He had never even heard of Telnet, didn't have a clue what it was -- and his news reports influence literally millions of Americans. BBS sysops and BBS system manufacturers need to refocus their efforts, and begin producing tools and content that take advantage of the Power of Telnet.

Third, Telnet Site operators (such as BBS sysops) must professionalize the look and feel of their systems. Most sysops make little investment in quality graphics for their systems. In a glitzy Web world, it is little wonder that the public is turned off by ANSI BBS systems no matter how if the content on them is of high quality. We constantly hear BBS sysops complain about having to pay what are very modest sums of money for RIPscrip graphics -- but the people running Web sites don't think twice about investing thousands of dollars for a fabulous look.

Despite all the flack we take from BBS sysops, we continue to support their efforts -- and we always will. But BBS sysops have to change with the times, and they have to be willing to invest to upgrade their systems to compete with (or complement) the Web.

On Christmas, TeleGrafix released the first multimedia Telnet browsers. RIPtel Visual Telnet is available now from our Web site at www.telegrafix.com. This is a huge step forward for the Internet, and it represents a salvation for BBS sysops by placing Telnet graphically on a higher level than the Web.

The serious professional operators will get on board the Visual Telnet train, and they will live to see a brighter day.

Source record: 99185

For sale: Two sets of Boonton 103A Standard Inductors.

Set 1: (Cans somewhat cruddy from long storage, but should clean up OK)
Ten inductors: O.25, 0.5, 1, 5, 35, 100, 500 microhenry
2.5, 10, 25 millihenry

Set 2: (Cans cleaner than Set 1)
Sixteen Inductors: 0.25, 0.5, 1, 2.5, 5, 10, 25, 50, 100, 250, 500
microhenry
1, 2.5, 5, 10, 25 millihenry

Set 1 has a labelled wooden mounting board that I don't really care to ship unless the buyer can't live without it! (The labels are frequency range for each coil.)

Prices: Set 1, $35 plus shipping
Set 2, $50 plus shipping Both sets for $75 plus
shipping.

Will deliver within 30 mi more or less from Palo Alto, CA

>faster not slower! Where have I gone wrong?
>73, Jesse, W6KKT

Hi, Jesse, Peter is correct. if you are trying to use a vacuum relay for QSK keying, you can easily measure that the release time is increased by the diode accross the coil. This problem is eliminated by putting a zener diode of the same voltage rating as the relay in series with the diode accross the coil...the band on the zener goes to the minus terminal on the relay. This limits the spike, saves the switching transistor, and speeds up the relay release time.

I have a paper by Sanjit K. Mitra ("Synthesizing active filters", IEEE Spectrum, vol. 6, pp. 47-63, Jan. 1969) which briefly mentions the twin-Tee. It refers to it as originating with a person named Moschytz, and references a paper which sounds like it has a lot more analysis. The paper (which I don't have) is Moschytz, G.S., "Miniaturized filter building blocks using frequency emphasizing networks", Proc. Nat'l Electron. Conf., pp. 364-369, 1967. If you can't find this you might look for other papers or books by this author. Good luck!

Is there any information on the web about building a 2 meter ssb receiver? I have the Sam "Radio Handbook" 23rd edition and "The ARRL Handbook..." 1993 edition. Both give schematic drawings for all the stages but not how to determine the values needed. I might have looked over that part of the book but I have been looking hard and reading. I am looking for a way to build a 2 meter ssb receiver for hearing the sat P3D. After I get the receiver working I plan to get to work on a 70cm ssb transmitter to work P3D when it's up and working, but only one project at a time. Thanks for any help you can give me.

Long Delayed Echo mysteries...

Hi,
I'm doing some research for a documentary about anomalies. One of the subjects I'm interested in is that of LDE's. I have done some reading on the subject and noted a few experiments - however, I'm looking for new information & experiences which may help to throw more light on the matter.

Of especial interest is the geographic "preferences" of LDEs. I noted for example that some evidence pointed to LDEs being more prevalent in the Polar regions. Do LDE's have any other preferences? Also, I'm interested in the various characteristics of the LDEs. I noted some saying that it tends to occur when "opening up" a frequency.

If you have had any experiences, or know of further literature or people I can consult - I would very much appreciate it.

I have posted this in several newsgroups since I wasn't quite sure which is the best place to go, so if this is out of place - I apologise.

If you can help in any way, kindly reply by e-mail. Thanks.

Cheers, Jan...

Message-ID: <01bbf76b$cacb40e0$b5b4e0c2@mariano>
Source record: 99051
Cross-posted to: rec.puzzles,rec.puzzles.crosswords,rec.pyrotechnics,rec.radio.amateur.antenna,rec.radio.amateur.digital.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.policy,rec.radio.amateur.space,rec.radio

Take five minutes to read this and it WILL change your life.

If you want to make big bucks ($50000+) without any effords, read this article and follow the instructions!

By investing just $5, you can and WILL get thousands of dollars by the mail.

It's REALLY SIMPLE to do!!!!

STEP 1.

Invest your $5 by writing your name and address on five seperate pieces of paper along with the words: "PLEASE ADD ME TO YOUR MAILING LIST."
(In this way, you're not just sending a dollar to someone; you're payingfor a legitimate service.) Fold a $1 bill inside each paper, and mail them by standard U. S. Mail to the following five addresses:

1-Sam Coice
25550 Buckthorn Ridge Rd
Pioneer Ca 95666

2-Peg Vickmore
14905 Highway 88
Jackson, Ca 95642

3-Brian Hyson
4278 Sayoko Cr
San Jose, Ca, 95136-2335 USA

4-Andres Camacho
Rua Apodi 78
Sao Paulo, SP, 05052-010 Brazil

5-Mariano Peinado
Apdo Correos 291
03730 Javea - Alicante -
Spain

STEP 2.

Now remove the top name from the list, and move the other names up. This way, #5 becomes #4 and so on.
Put your name in as the fifth one on the list.

STEP 3.

Post the article to "at least" 250 newsgroups. Rembering that
the more that you post on, the more people see it, and
the more you will get. There are at least 30,000 newsgroups
at any given moment in time so don't be stingy.

STEP 4.

You are now in business for yourself, and should start seeing
returns within 7 to 14 days! Remember, the Internet is new
and huge. There is no way you can lose.

Now here is how and why this system works:

Out of every block of 250 posts I made, I got back about 5
responses. Yes, thats right,only 5. You make $5.00 in cash,
not checks or money orders, but real cash with your name at
#5.

Each additional person who sent you $1.00 now also makes 250
additional postings with your name at #4, 1000 postings. On
average then, 50 people will send you $1.00 with your name at
#4,....$50.00 in your pocket!

Now these 50 new people will make 250 postings each with your
name at #3 or 10,000 postings. Average return, 500 people= $500.
They make 250 postings each with your name at #2= 100,000
postings=5000 returns at $1.00 each=$5,000.00 in cash!

Finally, 5,000 people make 250 postings each with your name at
#1 and you get a return of $60,000 before your name drops off
the list.And that's only if everyone down the line makes only 250
postings each! Your total income for this one cycle is $55,000.

From time to time when you see your name is no longer on the list,
you take the latest posting you can find and start all over again.

The end result depends on you. You must follow through
and repost this article everywhere you can think of.
The more postings you make, the more cash ends up in
your mailbox. It's too easy and too cheap to pass
up!!!

So thats it. Pretty simple sounding stuff, huh? But believe me, it
works. There are millions of people surfing the net every day, all
day, all over the world. And 100,000 new people get on the net
every day. You know that, you've seen the stories in the paper.
So, my friend, read and follow the simple instructions and play
fair. Thats the key, and thats all there is to it. Print this out
right now so you can refer back to this article easily. Try to
keep
an eye on all the postings you made to make sure everyone is
playing fairly. You know where your name should be.

If you're really not sure or still think this can't be
for real, then don't do it. But please print this article and pass
it along to someone you know who really needs the bucks, and see
what happens.

REMEMBER....HONESTY IS THE BEST POLICY.YOU DON'T
NEED TO CHEAT THE BASIC IDEA TO MAKE THE BUCKS!
GOOD LUCK TO ALL, AND PLEASE PLAY FAIR AND YOU WILL
WIN AND MAKE SOME REAL INSTANT FREE CASH!

*** By the way, if you try to deceive people by posting the messages
with your name in the list and not sending the bucks to the people
already included, you will not get much. I know someone who did this
and only got about $150 (and that's after two months). Then he sent
the 5 bills, people added him to their lists, and in 4-5 weeks he had
over $10,000!

TRY IT AND YOU'LL BE HAPPY!!! :o) !!!!!!!!!!

Hello,
I have an old Scott R-327 stereo reciever I am playing around with.
It works well in all modes except FM radio, where I can tune (stereo and
signal strength indicator high) but only hear the station with the volume
turned all the way up (along with a slight buzz). AM and CD input work
and sound great. If I spin the tuning dial it is louder as it goes by
a station but when I tune it is only very faint. I am treating this as
a test experiment for learning more about FM and would appreciate
where to begin. i.e., what components to check, what the probable
cause is, etc?

Thanks alot, this newsgroup is a great place to learn.

There was a paper in the Proceedings of the IRE in the 1950's that analyzed
all the permutations of the Bridged-T network. The title was something
to the effect of "An analysis of the bridged-T network". I suggest you
start with that. I have a copy somewhere. If I can, I'll post the exact
citation. The bridged-T network can do most if not all of what the twin T will do.

Another thing to keep in mind is that both of these networks are reduced
(i.e. unbalanced) forms of balanced lattices. The easiest thing to do
is design whatever you want as a balanced lattice network first, then use
lattice network theorems to unbalance and reduce it. You can find info
on balanced lattice networks in any advanced network theory book over 30
years old. These techniques, though largely unknown now, are extremely
powerful. You should be aware that you cannot realize a real right half
plane zero in an unbalanced network like a twin T or bridged T. Only a
balanced lattice (or half lattice) can do that. Other than that, you can
do just about anything you want quite easily, once you master the technique.

I agree that the test should reflect the current state of the hobby. Most of the guys will talk about tradition and using cw as a filter to keep the riffraff out but a more techical test that makes people actually learn something of electronics and operating procedures instead of memorizing the answers would be a much better filter. Then, you would have people who are genuinely interested in radio, and operating a radio instead of having access to a "glorified" CB.

> any info appreciated....
> 73,

Ron,
The 6293 is essentially a 6146 intended for "pulse-modulator" (i.e.
radar) service.
As per RCA in 4-63, Typical operation is:
DC Plate Supply Voltage 3000 Volts (!)
DC Grid-No.2 Supply Voltage 300 Volts
DC Grid-No.1 Supply Voltage -175 Volts
Peak Positive Grid-No.1 Voltage 65 Volts
Plate Current:
Peak 1.5 Amp (!)
Average 0.015 Amp
DC Grid-No.2 Current 0.004 Amp
DC Grid-No.1 Current 0.0025 Amp
Load Resistance, 100 watts 1500 Ohms

Naturally, these ratings apply to a very short duty cycle. Pin
connections, and filament voltage appear to be identical to a 6146.

>
> I do wonder where Richard got the formula [E1/E2]^23.5. Is the answer in
> hours, percent, seconds, or ratio? Where does it come from?
>
In paragraph two on page 141 in *Care and Feeding of Power Grid Tubes*,
regarding thoriated tungsten filaments, Eimac says that "Theoretically, a
3% increase in filament voltage will result in a 20 degree Kelvin increase
in temperature, a 20% increase in peak emission, and a 50% decrease in
life due to carbon loss. This or course, works the other way too. For a
small decrease in temperature and peak emission, life of the carbide layer
and hence tube life can be increased by a substantial percentage."

In other words, for every 3% increase in filament voltage above what is
needed, a 50% decrease in emissive life results. The formula [E1/E2]^23.4
is the algebraic representation thereof. The result is the ratio of
useful emissive life. (However, filament voltage should not be decreased
to the point where pep begins to decrease.)

Applying [E1/E2]^23.4 to an actual case: The factory-stock TL-922
amplifier applies 5.3v to the 3-500Z filaments. However, a healthy 3-500Z
will operate quite satisfactorily in communications service with 4.75v on
the filament. Using the formula: [4.75v/5.3v]^23.4 = ¦0.8962]^23.4 =

0.077. In other words, by operating the filaments at 5.3v at instead of 4.75v, emissive life is reduced to about 8% of what could be achived at the lower filament voltage. Of course, in actual practice, this is not quite realizeable because the filament voltage normally needs to be increased as the tube nears the end of its useful emissive life. Thus, a rheostat to control filament voltage is is rather useful. However, to the best of my knowledge, none of the commercial manufacturers provide a means of adjusting filament voltage. Art Collins typically provided a means of adjusting an amplifier's filament voltage.

I pretty much covered this on pages 30 and 31 of "The Nearly Perfect Amplifier" in the January, 1994 issue of QST magazine. Does it seem likely that someone who askes the question "Where does it come from?" has read the"The Nearly Perfect Amplifier"?

In the September 1994 issue of QST magazine, Mr. Rauch criticized the article in question, apparently without the benefit of having read at least two pages of the five page article. In the October 1994 issue of QST magazine, MFJ/Ameritron took out over 30 full pages of QST advertising.

The coherer was indeed a detector. It was a small glass tube filled
with fine iron powder, with electrodes at each end of the tube. The
incoming signal caused the iron powder to stick together (cohere). I'm
not exactly sure why. Connected to the same terminals was another circuit
that operated a telegraph sounder. Once the powder "cohered" it wanted to
stay that way, even though the incoming signal was not there, so the clock
wound mechanism was a "tapper" that tapped the side of the glass tube and
broke the iron powder granules up when the signal stopped. The coherer
was NOT very sensitive. More sensitive was a rectifier diode made by just
barely touching the surface of a nitric acid bath with a platinum wire and
then drawing the wire out until only a thin meniscus of acid extended from
the surface of the acid to the wire. The platinum wire slowly got eaten
away and required continuous adjustment for optimum sensitivity. The
presence of an open container of nitric acid on top of the operating table
was a hazard too. :-) Connections to the wire and to an electrode in the
acid bath were the two terminals of the diode. The galena (lead sulfide)
detector beat both of these.
By the way, I'm only 55, so I wasn't around in those halycon days of
yore. :-) :-)

>of a given combination of R and C?

Roy L. posted the formula, but there's more that should be added to the story. If you want a very sharp cutoff, you really need to build a filter with resonances (poles) with specific characteristics you will not be able to get from just passive RC filters. But if you put R's and C's in the proper circuit as feedback around amplifiers, you can get the overall circuit to perform essentially the same task as LC circuits. The RC circuits are good for low frequency filters, but don't expect with even good op amps to get much of an active filter above a megahertz or so. The formula you'd use for RC networks in feedback amplifiers depends on the specific configuration, and I'd advise you to look up a book on active filter design. There are dozens of different ones,
from simple cookbooks to very theoretical.

Hi Rich!

By "high value", do you mean 100k+? Or more than $0.25 a piece? <g>

Thanks for the suggestion!

I recently acquired two GE porta-mobil radios. These were originally used on 44 mhz by the Tennessee Forestry Service. I would like to convert them to 6 meters but I dont have the schematics on them. The model# was worn on both of them but i could make out a FCC # which was hr44las33 if that helps any. They disconnect in the middle. The lower half is a power supply and the upper half is the tranciever. Possibly the upper half may have plugged into a module for mobile use but im not sure. Anyone having schematics or if anyone has done a 6 meter conversion with these rigs any info will be appreciated

Thanks
Paul

Sounds like a problem with the low level audio buffers at the output
of the stereo multiplex decoder although its unlikely that both
channels would fail at the same time. It could also be the stereo
decoder itself, which could knock out both channels if there were
a failure. Not sure if your receiver is new enough to have ICs in it
but if it does, you can generally find the pinouts for the stereo
decoder IC in the RCA-SK or NTE semiconductor replacement catalogs.
(NTE has a website). Use a scope to look at the input to the decoder
IC. You should see mono audio with a 19KHz pilot carrier riding on it.
At the left and right outputs from the decoder you should have decoded
stereo audio at a reasonable level (say 100mV p-p or more).
If everything is OK to that point, its probably the buffer amps
between the decoder and the power amplifier.

There are some newsgroups for audio out there. I would talk it up in
those and do a web search to try and find a schematic
which will help with your trouble shooting. I think SAMS still sells
their PhotoFact schematics but they have always been expensive.

Good luck

Steve M. WF6R

David-------
The vertical is two half waves in phase for 20m. This is also known as a Franklin Antenna. The antenna is mounted on the roof of a wooden toolshed. It is fed at roof level against a quarter wave counterpoise. The feed Z is around 700 ohms. The bleeder resistor is 10meg-ohms. This resistor can tolerate several kilovolts.

There were many different types of coherers, most of which used iron
filings. The Marconi used Nickel and Silver filings, the Solari used
mercury and some others used carbon. These things were used from the
1880's to the early 1900's.

If you want more specific info contact the Antique Wireless Association
(AWA). http://www.ggw.org/freenet/a/awa/

Another fact almost escaped your great storehouse of knowledge, hi! EVERY
Ameritron PA after the early to mid 80's includes taps for adjusting
filament voltage, and instructions for the proper settings for each line
voltage range.

Can anyone confirm Rich's claims the TL-922 has short tube emission life?
I wonder what the tube experience of 922 owners really is. How many 922
owners have replaced tubes from:

low emission (everything works but output is real low)
gas or anode support failure (a sudden loud bang or pop, or an arc in the
tube)
an internal grid short (idle current even when on standby and no output)

Has anyone else measured the voltage to confirm Rich's story? How about
other PA's?

BTW....I did read your article Rich, I'm afraid I just learned to question
any information presented as an absolute "fact". I mostly agree with your
filament approximation, IF the voltages you presented here are the true
voltages in the Kenwood PA.

I'm sure you understand why I ask these questions. I want to be sure the
facts you state here are verifiable by other independent sources.
